(54) Title: CONTROL OF PROTEIN SYNTHESIS, AND SCREENING METHOD FOR AGENTS

(57) Abstract

A method for screening for agents capable of affecting the activity of kinases GSK3 and PKB is disclosed. The method involves assessing the phosphorylation of PKB on two amino acids on the PKB molecule particularly.

1

Control of protein synthesis, and screening method for 1 agents. 2 3 The present invention relates to the control of 4 glycogen metabolism and protein synthesis, in 5 particular through the use of insulin. 6 7 Many people with diabetes have normal levels of insulin 8 in their blood, but the insulin fails to stimulate 9 muscle cells and fat cells in the normal way (type II 10 diabetes). Currently it is believed that there is a 11 breakdown in the mechanism through which insulin 12 signals to the muscle and fat cells. 13 14 The enzyme glycogen synthase kinase-3 (GSK3) (Embi et 15 al., 1980) is implicated in the regulation of several 16 physiological processes, including the control of 17 glycogen (Parker et al., 1983) and protein (Welsh et 18 al., 1993) synthesis by insulin, modulation of the 19 transcription factors AP-1 and CREB (Nikolaki et al, de 20 Groot et al., 1993 and Fiol et al 1994), the 21 specification of cell fate in Drosophila (Siegfied et 22 al., 1992) and dorsoventral patterning in Xenopus 23 embryos (He et al., 1995). GSK3 is inhibited by serine 24

2

phosphorylation in response to insulin or growth 1 factors (Welsh et al., 1993, Hughes et al., 1994, Cross 2 et al., 1994 and Saito et al., 1994) and in vitro by 3 either MAP kinase-activated protein (MAPKAP) kinase-1 4 (also known as p90^{nk}) or P70 ribosomal S6 kinase (p70^{S6k}) 5 (Sutherland et al., 1993 and Sutherland et al., 1994). 6 7 We have now found, however, that agents which prevent 8 the activation of both MAPKAP kinase-1 and p70^{sok} by 9 insulin in vivo do not block the phosphorylation and 10 inhibition of GSK3. Another insulin-stimulated protein 11 kinase inactivates GSK3 under these conditions, and we 12 demonstrate that it is the product of the proto-13 oncogene Akt (also known as RAC or PKB; herein referred 14 15 to as "PKB"). 16 GSK3 is inhibited in response to insulin with a half 17 time of two min, slightly slower than the half time for 18 activation of PKB α (one min). Inhibition of GSK3 by 19 insulin results in its phosphorylation at the same 20 serine residue (serine 21) which is targeted by PKBa in 21 vitro. Like the activation of PKBa, the inhibition of 22 GSK3 by insulin is prevented by phosphatidyl inositol 23 (PI-3) kinase inhibitors wortmannin and LY 294002. The 24 inhibition of GSK3 is likely to contribute to the 25 increase in the rate of glycogen synthesis (Cross et 26 al., 1994) and translation of certain mRNAs by insulin 27 (Welsh et al., 1994). 28 29 Two isoforms of PKB, termed PKBa (Coffer & Woodgett, 30 1991), PKB β (Cheng et al., 1992) and PKB γ (Konishi et 31 al., 1995) have been identified and characterised. 32 PKBeta, also known as RACeta and Akt-2, is over-expressed 33 in a significant number of ovarian (Cheng et al., 1992) 34 and pancreatic (Cheng et al., 1996) cancers and is 35 over-expressed in the breast cancer epithelial cell 36

3

line MCF7. PKB is composed of an N-terminal pleckstrin 1 homology (PH) domain, followed by a catalytic domain 2 and a short C-terminal tail. The catalytic domain is 3 most similar to cyclic AMP-dependent protein kinase 4 (PKA, 65% similarity) and to protein kinase C (PKC, 75% 5 similarity) findings that gave rise to two of its 6 names, namely PKB (i.e. between PKA and PKC) and RAC 7 (Related to A and C kinase). 8 9 Many growth factors trigger the activation of 10 phosphatidylinositol (PI) 3-kinase, the enzyme which 11 converts PI 4,5 bisphosphate (PIP2) to the putative 12 second messenger PI 3,4,5 trisphosphate (PIP3), and PKB 13 lies downstream of PI 3-kinase (Franke et al., 1995). 14 $PKB\alpha$ is converted from an inactive to an active form 15 with a half time of about one minute when cells are 16 stimulated with PDGF (Franke et al., 1995), EGF or 17 basic FGF (Burgering & Coffer, 1995) or insulin (Cross 18 et al., 1995 and Kohn et al., 1995) or perpervanadate 19 (Andjelkovic et al., 1996). Activation of PKB by 20 insulin or growth factors is prevented if the cells are 21 preincubated with inhibitors of PI 3-kinase (wortmannin 22 or LY 294002) or by overexpression of a dominant 23 negative mutant of PI 3-kinase (Burgering & Coffer 24 1995). Mutation of the tyrosine residues in the PDGF 25 receptor that when phosphorylated bind to PI 3-kinase 26 also prevent the activation of PKBα (Burgering & 27 Coffer, 1995 and Franke et al., 1995). 28 29 The present invention thus provides the use of PKB, its 30 analogues, isoforms, inhibitors, activators and/or the 31 functional equivalents thereof to regulate glycogen 32 metabolism and/or protein synthesis, in particular in 33 disease states where glycogen metabolism and/or protein 34 synthesis exhibits abnormality, for example in the 35 treatment of type II diabetes; also in the treatment of 36

4

cancer, such as ovarian, breast and pancreatic cancer. 1 A composition comprising such agents is also covered by 2 the present invention, and the use of such a 3 composition for treatment of disease states where glycogen metabolism and/or protein synthesis exhibit 5 abnormality. 6 7 The present invention also provides a novel peptide 8 comprising the amino acid sequence Arg-Xaa-Arg-Yaa-Zaa-9 Ser/Thr-Hyd, where Xaa is any amino acid, Yaa and Zaa 10 are any amino acid (preferably not glycine), and Hyd is 11 a large hydrophobic residue such as Phe or Leu, or a 12 functional equivalent thereof. Represented in single 13 letter code, a suitable peptide would be RXRX'X'S/TF/L, 14 where X' can be any amino acid, but is preferably not 15 glycine; glycine can in fact be used, but other amino 16 Typical peptides include acids are preferred. 17 GRPRTSSFAEG, RPRAATC or functional equivalents thereof. 18 The peptide is a substrate for measuring PKB activity. 19 20 The invention also provides a method for screening for 21 substances which inhibit the activation of PKB in vivo 22 by preventing its interaction with PIP3 or PI3,4-bisP. 23 24 Thus the invention also provides a method of 25 determining the ability of a substance to affect the 26 activity or activation of PKB, the method comprising 27 exposing the substance to PKB and phosphatidyl inositol 28 polyphosphate (ie PIP3, PI3,4-bisP etc) and determining 29 the interaction between PKB and the phosphatidyl 30 inositol polyphosphate. The interaction between PKB 31 and the phosphatidyl inositol polyphosphate can 32 conveniently be measured by assessing the 33 phosphorylation state of PKB (preferably at T308 and/or 34 S473), eg by measuring transfer of radiolabelled 32P 35 from the PIP3 (for example) to the PKB and/or by SDS-36

5

PAGE. 1 2 The method of the invention can also be used for 3 identifying activators or inhibitors of GSK3, such a 4 method can comprise exposing the substance to be tested 5 to GSK3, and (optionally) a source of phosphorylation, 6 and determining the state of activation of GSK3 7 (optionally by determining the state of its 8 phosphorylation. This aspect of the invention can be 9 useful for determining the suitability of a test 10 substance for use in combatting diabetes, cancer, or 11 any disorder which involves irregularity of protein 12 synthesis or glycogen metabolism. 13 14 The invention also provides a method for screening for 15 inhibitors or activators of enzymes that catalyse the 16 phosphorylation of PKB, the method comprising exposing 17 the substance to be tested to 18 - one or more enzymes upstream of PKB; 19 - PKB; and (optionally) 20 - nucleoside triphosphate 21 and determining whether (and optionally to what extent) 22 the PKB has been phosphorylated on T308 and/or S473. 23 24 Also provided is a method of identifying agents able to 25 influence the activity of GSK3, said method comprising: 26 27 exposing a test substance to a substrate of GSK3; 28 a. 29 detecting whether (and, optionally, to what b. 30 extent) said peptide has been phosphorylated. 31 32 The test substance may be an analogue, isoform, 33 inhibitor, or activator of PKB, and the above method 34 may be modified to identify those agents which 35 stimulate or inhibit PKB itself. Thus such a method 36

6

may comprise the following steps: 1 2 exposing the test substance to a sample containing 3 a. PKB, to form a mixture; 4 5 exposing said mixture to a peptide comprising the b. 6 amino acid sequence defined above or a functional 7 equivalent thereof (usually in the presence of Mg2+ 8 and ATP); and 9 10 detecting whether (and, optionally, to what 11 C. extent) said peptide has been phosphorylated. 12 13 In this aspect the method of the invention can be used 14 to determine whether the substance being tested acts on 15 PKB or directly on GSK3. This can be done by comparing 16 the phosphorylation states of the peptide and PKB; if 17 the phosphorylation state of GSK3 is changed but that 18 of PKB is not then the substance being tested acts 19 directly on GSK3 without acting on PKB. 20 In a further aspect the present invention provides a 21 method of treatment of the human or non-human 22 (preferably mammalian) animal body, said method 23 comprising administering PKB, its analogues, 24 inhibitors, stimulators or functional equivalents 25 thereof to said body. Said method affects the 26 regulation of glycogen metabolism in the treated body. 27 28 The method of treatment of the present invention may be 29 of particular use in the treatment of type II diabetes 30 (where desirably an activator of PKB is used, so that 31 the down-regulation of GSK3 activity due to the action 32 of PKB is enhanced). 33 34 The method of treatment of the present invention may 35

35 The method of treatment of the present invention may 36 alternatively be of particular use in the treatment of

7

cancer such as ovarian cancer (where desirably an 1 inhibitor of PKB is used, so that the down-regulation 2 of GSK3 activity due to the action of PKB is 3 depressed). Other cancers associated with 4 irregularities in the activity of PKB and/or GSK3 may 5 also be treated by the method, such as pancreatic 6 cancer, and breast cancer. 7 8 Stimulation of PKB with insulin increases activity 9 12-fold within 5 min and induces its phosphorylation at 10 Thr-308 and Ser-473. PKB transiently transfected into 11 cells can be activated 20-fold in response to insulin 12 and 46-fold in response to IGF-1 and also became 13 phosphorylated at Thr-308 and Ser-473. The activation 14 of PKB and its phosphorylation at both Thr-308 and 15 Ser-473 can be prevented by the phosphatidylinositol 16 (Pl) 3-kinase inhibitor wortmannin. 17 phosphorylation of threonine 308 and serine 473 act 18 synergistically to activate PKB. 19 20 MAPKAP kinase-2-phosphorylated PKB at Ser-473 in vitro 21 increases activity seven-fold, an effect that can be 22 mimicked (fivefold activation) by mutating Ser-473 to 23 Asp. Mutation of Thr-308 to Asp also increases PKB 24 activity five-fold and subsequent phosphorylation of 25 Ser-473 by MAPKAP kinase-2 stimulates activity a 26 further fivefold, an effect mimicked (18-fold 27 activation) by mutating both Thr-308 and Ser-473 to 28 Asp. The activity of the Asp-308/Asp-473 double mutant 29 was similar to that of the fully phosphorylated enzyme 30 and could not be activated further by insulin. Mutation 31 of Thr-308 to Ala did not prevent the phosphorylation 32 of transfected PKB at Ser-473 after stimulation of 293 33 cells with insulin or IGF-1, but abolished the 34 activation of PKB. Similarly, mutation of Ser-473 to 35 Ala did not prevent the phosphorylation of transfected 36

8

PKB at Thr-308 but greatly reduced the activation of 1 transfected PKB. This demonstrates that the activation 2 of PKB by insulin or IGF-1 results from the 3 phosphorylation of Thr-308 and Ser-473 and that phosphorylation of both residues is preferred to 5 generate a high level of PKB activity in vitro or in 6 vivo. Also, phosphorylation of Thr-308 in vivo is not 7 dependent on the phosphorylation of Ser-473 or vice versa, that the phosphorylation of Thr-308 and Ser-473 9 are both dependent on PI 3-kinase activity and suggest 10 that neither Thr-308 nor Ser-473 phosphorylation is 11 catalysed by PKB itself. 12 13 Thus, it is preferred that the present invention 14 incorporates the use of any agent which affects 15 phosphorylation of PKB at amino acids 308 and/or 473, 16 for example insulin, inhibitors of PI 3-kinase such as 17 wortmannin or the like. The use of PKB, itself altered 18 at amino acids 308 and/or 473 (eg by phosphorylation 19 and/or mutation) is also suitable. 20 21 In a variation of the method of the present invention, 22 stimulation or inhibition of PKB may be assessed by 23 monitoring the phosphorylation states of amino acids 24 308 and/or 473 on PKB itself. 25 26 Different isoforms of PKB may be used or targeted in 27 the present invention; for example PKB α , β or γ . 28 29 The present invention will now be described in more 30 detail in the accompanying examples which are provided 31 by way of non-limiting illustration, and with reference 32 to the accompanying drawings. 33 34 Example 1:PKB influences GSK3 activity. 35 Fig 1: a, L6 myotubes were incubated for 15 min with 2 36

9

mM 8-bromocyclic-AMP (8Br-cAMP) and then with 0.1 μ M 1 insulin (5 min). Both GSK3 isoforms were co-2 immunoprecipitated from the lysates and assayed before 3 (black bars) and after (white bars) reactivation with 4 PP2A (Cross et al., 1994). The results are presented 5 relative to the activity in unstimulated cells, which 6 was 0.08 ± 0.006 U mg⁻¹ (n=10). 7 b, c, The inhibition of GSK3 by insulin (0.1 μ M) is 8 unaffected by rapamycin (0.1 μM) and PD 98059 (50 μM), 9 but prevented by LY 294002 (100 μ M). 10 11 b, L6 myotubes were stimulated with insulin for the 12 times indicated with (filled triangle) or without 13 (filled circles) a 15 min preincubation with LY 294002, 14 and GSK3 measured as in a. The open circles show 15 experiments from insulin-stimulated cells where GSK3 16 was assayed after reactivation with PP2A (Cross et al., 17 1994). 18 19 c, cells were incubated with rapamycin (triangles) or 20 rapamycin plus PD 98059 (circles) before stimulation 21 with insulin, and GSK3 activity measured as in a, 22 before (filled symbols) and after (open symbols) 23 pretreatment with PP2A. 24 25 d, e, L6 myotubes were incubated with 8Br-cAMP (15 min) 26 PD 98059 (60 min) or LY 294002 (15 min) and then with 27 insulin (5 min) as in a-c. Each enzyme was assayed 28 after immunoprecipitation from lysates, and the results 29 are presented relative to the activities obtained. 30 the presence of insulin and absence of 8Br-cAMP, which 31 were 0.04±0.005 U mg⁻¹ (p42 MAP kinase, n=6) and 0.071 ± 32 0.004 U mg-1 (MAPKAP Kinase-1, n=6). 33 34 All the results (± s.e.m.) are for at least three 35 experiments. 36

10

Monolayers of L6 cells were cultured, stimulated and 1 lysed as described previously (Cross et al., 1994). 2 p42 MAP kinase, MAPKAP kinase 1 or (GSK3- α plus GSK3- β) 3 were then immunoprecipitated from the lysates and 4 assayed with specific protein or peptide substrates as 5 described previously (Cross et al., 1994). One unit of 6 protein kinase activity was that amount which catalysed 7 the phosphorylation of 1 nmol of substrate in 1 min. 8 Where indicated, GSK3 in immunoprecipitates was 9 reactivated with PP2A (Cross et al., 1994). 10 11 12 Figure 2 Identification of PKB as the insulin-13 stimulated, wortmannin-sensitive and PD 14 98059/rapamycin-insensitive Crosstide kinase in L6 15 myotubes. 16 a. Cells were incubated with 50 μM PD 98059 (for 1 17 hour) and 0.1 μM rapamycin (10 min), then stimulated 18 with 0.1 μM insulin (5 min) and lysed (Cross et al., 19 1994). The lysates (0.3 mg protein) were 20 chromatographed on Mono Q (5 x 0.16cm) and fractions 21 (0.05ml) were assayed for Crosstide kinase (filled 22 circles). In separate experiments insulin was omitted 23 (open circles) or wortmannin (0.1 μ M) added 10 min 24 before the insulin (filled triangles). The broken line 25 shows the NaCl gradient. Similar results were obtained 26 in six experiments. 27 28 b. Pooled fractions (10 μ l) 31-34 (lane 1), 35-38 (lane 29 2), 39-42 (lane 3), 43-45 (lane 4), 46-49 (lane 5) and 30 50-53 (lane 6) from a were electrophoresed on a 10% 31 SDS/polyacrylamide gel and immunoblotted with the C-32 terminal anti-PKBa antibody. Marker proteins are 33 indicated. No immunoreactive species were present in 34 fractions 1-30 or 54-80. 35 36

11

c. L6 myotubes were stimulated with 0.1 μM insulin and 1 PKB immunoprecipitated from the lysates (50 μ g protein) 2 essentially as described previously (Lazar et al., 3 1995), using the anti-PH domain antibody and assayed 4 for Crosstide kinase (open circles). In control 5 experiments, myotubes were incubated with 0.1 μM 6 rapamycin plus 50 μ M PD 98059 (open triangles) or 2 mM 7 8Br-cAMP (open squares), or 0.1 μ M wortmannin (filled 8 circles) or 100 μ M LY 294002 (filled triangles) before 9 stimulation with insulin. 10 11 d. As c, except that MAPKAP kinase-1 was 12 immunoprecipitated from the lysates and assayed with S6 13 peptide (filled circles). In control experiments, 14 cells were incubated with 0.1 μM rapamycin plus 50 μM 15 PD 98059 (filled triangles) or with 2 μM 8BR-cAMP (open 16 circles) before stimulation with insulin. In c and d, 17 the error bars denote triplicate determinations, and 18 similar results were obtained in three separate 19 experiments. 20 21 Mono Q chromatography was performed as described 22 (Burgering et al., 1995), except that the buffer also 23 contained 1 mM EGTA, 0.1 mM sodium orthovanadate and 24 0.5% (w/v) Triton X-100. Two PKB α antibodies were 25 raised in rabbits against the C-terminal peptide 26 FPQFSYSASSTA and bacterially expressed PH domain of 27 The C-terminal antibody was affinity purified 28 (Jones et al., 1991). The activity of PKB towards 29 Crosstide is threefold higher than its activity towards 30 histone H2B and 11-fold higher than its activity 31 towards myelin basic protein, the substrates used 32 previously to assay PKB. Other experimental details 33 and units of protein kinase activity are given in 34 Fig 1. 35 36

12

Figure 3 GSK3 is inactivated by PKB from insulin-1 stimulated L6 myotubes. 2 a. Cells were stimulated for 5 min with 0.1 μ M insulin, 3 and PKB immunoprecipitated from 100 μ g of cell lysate 4 and used to inactivate GSK3 isoforms essentially as 5 described previously (Sutherland et al., 1993 and 6 Sutherland et al., 1994). The black bars show GSK3 7 activity measured after incubation with MgATP and PKB 8 as a percentage of the activity obtained in control 9 incubations where PKB was omitted. In the absence of 10 PKB, GSK3 activity was stable throughout the 11 experiment. The white bars show the activity obtained 12 after reactivation of GSK3 with PP2A (Embi et al., 13 1980). No inactivation of GSK3 occurred if insulin was 14 omitted, or if wortmannin (0.1 \(\mu M \) was added 10 min 15 before the insulin, or if the anti-PKB antibody was 16 incubated with peptide immunogen (0.5 mM) before 17 immunoprecipitation. The results (± s.e.m.) are for 18 three experiments (each carried out in triplicate). 19 20 b. Inactivation of GSK3- β by HA-PKB α . Complementary 21 DNA encoding HA-PKBa was transfected into COS-1 cells, 22 and after stimulation for 15 min with 0.1 mM sodium 23 pervanadate the tagged protein kinase was 24 immunoprecipitated from 0.3 mg of lysate and incubated 25 for 20 min with GSK3- β and MqATP. In control 26 experiments, pervanadate was omitted, or wildtype (WT) 27 PKBa replaced by vector (mock translation) or by a 28 kinase-inactive mutant of $PKB\alpha$ in which Lys 179 was 29 mutated to Ala (K179A). Similar results were obtained 30 in three separate experiments. The levels of WT and 31 K179A-PKBα in each immunoprecipitate were similar in 32 each transfection. 33 34 In a GSK3- α and GSK3- β were partially purified, 35 assayed, inactivated by PKB, and reactivated by PP2A 36

13

from rabbit skeletal muscle as described previously 1 (Sutherland et al., 1993 and Sutherland et al., 2 There was no reactivation in control 3 experiments in which okadaic acid (2 μ M) was added 4 before PP2A. 5 6 Figure 4: Identification of the residues in GSK3 7 phosphorylated by PKB in vitro and in response to 8 insulin in L6 myotubes. 9 a. GSK3-eta was maximally inactivated by incubation with 10 PKB and Mg-[γ -32P]ATP and after SDS-PAGE, the 32P-11 labelled GSK3- β (M, 47K) was digested with trypsin¹¹ and 12 chromatographed on a C18 column (Sutherland et al., 13 Fractions (0.8 ml) were analysed for 32P-14 radioactivity (open circles), and the diagonal line 15 shows the acetonitrile gradient. 16 17 b. The major phosphopeptide from a (400 c.p.m.) was 18 subjected to solid-phase sequencing (Sutherland et al., 19 1993), and 32P-radioactivity released after each cycle 20 of Edman degradation is shown. 21 22 c. GSK3- α and GSK3- β were co-immunoprecipitated from 23 the lysates of 32P-labelled cells, denatured in SDS, 24 subjected to SDS-PAGE, transferred to nitrocellulose 25 and autoradiographed (Saito et al., 1994). Lanes 1-3, 26 GSK3 isoforms immunoprecipitated from unstimulated 27 cells; lanes 4-6, GSK3 isoforms immunoprecipitated from 28 insulin-stimulated cells. 29 30 d. GSK3 isoforms from c. were digested with trypsin, 31 and the resulting phosphopeptides separated by 32 isoelectric focusing (Saito et al., 1994) and 33 identified by auto-radiography. Lanes 1 and 4 show the 34 major phosphopeptide resulting from in vitro 35 phosphorylation of GSK3-eta by PKB and MAPKAP kinase-1, 36

PCT/GB96/03186 WO 97/22360

14

respectively; lanes 2 and 5, the phosphopeptides 1 obtained from GSK3- β and GSK3- α , immunoprecipitated 2 from unstimulated cells; lanes 3 and 6, the 3 phosphopeptides obtained from GSK3- β and GSK3- α 4 immunoprecipitated from cells stimulated for 5 min with 5 0.1 µM insulin; the arrow denotes the peptides whose 6 phosphorylation is increased by insulin. The pI values 7 of two markers, Patent Blue (2.4) and azurin (5.7) are 8

9 10

In a. PKBa was immunoprecipitated with the C-terminal 11 antibody from the lysates (0.5 mg protein) of insulin-12 stimulated L6 myotubes and used to phosphorylate GSK-13 β^{12} . In c. three 10-cm diameter dishes of L6 myotubes 14 were incubated for 4 hours in HEPES-buffered saline 15 (Cross et al., 1994) containing 50 μ M PD 98059, 100 nM 16 rapamycin and 1.5 mCI ml-1 32P-orthophosphate, stimulated 17 for 5 min with insulin (0.1 μ M) or buffer, and GSK3 18 isoforms co-immunoprecipitated from the lysates as in 19 Fig 1. 20

21

36

Discussion.

indicated.

22 Inhibition of GSK3 induced by insulin in L6 myotubes 23 (Fig 1a-c) was unaffected by agents which prevented the 24 activation of MAPKAP kinase-1 (8-bromo-cyclic AMP, or 25 PD 98059 (Alessi et al., 1995), (Fig 1d,e) and/or p70^{Sók} 26 (rapamycin (Kuo et al., 1992)) (Cross et al., 1994), 27 suggesting that neither MAPKAP kinase-1 nor p70 set are 28 essential for this process. However, the 29 phosphorylation and inhibition of GSK3- β after phorbol 30 ester treatment (Stambolic et al., 1994) is enhanced by 31 coexpression with MAPKAP kinase 1 in HeLa S3 cells, 32 whereas in NIH 3T3 cells the EGF-induced inhibition of 33 GSK3- α and GSK3- β (Saito et al., 1994) is largely 34 suppressed by expression of a dominant-negative mutant 35 of MAP kinase kinase-1 (Elgar et al., 1995). MAPKAP

PCT/GB96/03186

kinase-1 may therefore mediate the inhibition of GSK3 1 by agonists which are much more potent activators of 2 the classical MAP kinase pathway than is insulin. 3 To identify the insulin-stimulated protein kinase that 5 inhibits GSK3 in the presence of rapamycin and PD 6 98059, L6 myotubes were incubated with both compounds 7 and stimulated with insulin. The lysates were then 8 chromatographed on Mono Q and the fractions assayed 9 with "Crosstide" (GRPRTSSFAEG), a peptide corresponding 10 to the sequence in GSK3 surrounding the serine 11 (underlined) phosphorylated by MAPKAP kinase-1 and p70 s6k 12 (Ser 21 in GSK3- α (Sutherland et al., 1994) and Ser 9 13 in GSK3- β (Sutherland et al 1993)). Three peaks of 14 Crosstide kinase activity were detected, which were 15 absent if insulin stimulation was omitted or if the 16 cells were first preincubated with the PI 3-kinase 17 inhibitor wortmannin (Fig 2a). Wortmannin (Cross et 18 al., 1994 and Welsh et al 1994), and the structurally 19 unrelated PI 3-kinase inhibitor LY 294002 (ref 19); 20 (Fig 1b), both prevent the inhibition of GSK3 by 21 insulin. 22 23 The protein kinases PKB-lpha, PKB-eta and PKB γ are Ser/Thr-24 specific and cellular homologues of the viral oncogene 25 v-akt (Coffer et al., 1991, Jones et al 1991, Ahmed et 26 al 1995 and Cheng et al., 1992). These enzymes have 27 recently been shown to be activated in NIH 3T3, Rat-1 28 or Swiss 3T3 cells in response to growth factors or 29 insulin, activation being suppressed by blocking the 30 activation of PI 3-kinase in different ways (Franke et 31 al., 1995 and Burgering et al., 1995). All three peaks 32 of Crosstide kinase (Fig 2a), but no other fraction 33

of PKB (relative molecular mass, M, 58K, 59K or 60K)
that have been observed in other cells, when

34

from Mono Q, showed the characteristic multiple bands

immunoblotting was performed with an antibody raised 1 against the carboxyl-terminal peptide of PKB- α (Fig 2 The more slowly migrating forms represent more 3 highly phosphorylated protein, and are converted to the 4 fastest migrating species by treatment with 5 phosphatases. Phosphatase treatment also results in 6 the inactivation of PKB (Burgering et al., 1995) and 7 the complete loss of Crosstide kinase activity (data 8 not shown). Of the Crosstide kinase activity in peaks 9 2 and 3 from Mono Q, 70-80% was immunoprecipitated by a 10 separate antibody raised against the amino-terminal 11 pleckstrin homology (PH) domain of PKB- α . 12 terminal antibody also immunoprecipitated PKB activity 13 specifically from peaks 2 and 3, but was less effective 14 than the anti-PH-domain antibody. Peak-1 was hardly 15 immunoprecipitated by either antibody and may represent 16 An immunoprecipitating anti-MAPKAP kinase-1 17 antibody (Cross et al., 1994) failed to deplete any of 18 the Crosstide kinase activity associated with peaks 1, 19 20 2 or 3. 21 Insulin stimulation of L6 myotubes increased PKB 22 activity by more than tenfold (Fig 2c), and activation 23 was blocked by wortmannin or LY 294002, but was 24 essentially unaffected by 8-bromo-cyclic AMP or 25 rapamycin plus PD 98059 (Fig 2c). The half-time $(t_{0.5})$ 26 or activation of PKB (1 min) was slightly faster than 27 that for inhibition of GSK3 (2 min) (Cross et al., 28 1994). In contrast, the activation of MAPKAP kinase-1 29 (Fig 2d) and p70^{S6k} (not shown) was slower ($t_{0.5} > 5$ min). 30 Activation of MAPKAP kinase-1 was prevented by 8-bromo-31 cyclic AMP or PD 98059 (Fig 2d), and activation of p7056k 32 by rapamycin (Cross et al., 1994). Akt/RAC 33 phosphorylated the Ser in the Crosstide equivalent to 34 Ser 21 in GSK3- α and Ser 9 in GSK3- β (data not shown). 35 36

PKB from insulin-stimulated L6 myotubes (but not from 1 unstimulated or wortmannin-treated cells) inactivated 2 GSK3- α and GSK3- β in vitro, and inhibition was reversed 3 by the Ser/Thr-specific protein phosphatase PP2A (Embi 4 et al., 1980) (Fig 3a). To further establish that 5 inactivation was catalysed by PKB, and not by a co-6 immunoprecipitating protein kinase, haemagglutonin-7 tagged PKB- α (HA-PKB) was transfected into COS-1 cells 8 and activated by stimulation with pervanadate, which is 9 the strongest inducer of PKB activation in this system. 10 The HA-PKB inactivated GSK3- β , but not if treatment 11 with pervanadate was omitted or if wild-type HA-PKB was 12 replaced with a "kinase inactive" mutant (Fig 3b). 13 14 The inactivation of GSK3- β by PKB in vitro was 15 accompanied by the phosphorylation of one major tryptic 16 peptide (Fig 4a) which coeluted during C_{18} 17 chromatography (Sutherland et al., 1993) and 18 isoelectric focusing with that obtained after 19 phosphorylation by MAPKAP kinase-1 (Fig 4d). 20 Stimulation of L6 myotubes with insulin (in the 21 presence of rapamycin and PD 98059) increased the 32P-22 labelling of GSK3- α and GSK3- β by 60-100% (Fig 4c) and 23 increased the 32P-labelling of the same tryptic peptides 24 labelled in vitro (Fig 4d). Sequence analyses 25 established that the third residue of these, 26 corresponding to Ser 9 (GSK3- β) or Ser 21 (GSK3- α), was 27 the site of phosphorylation in each phosphopeptide, 28 both in vitro (Fig 4b) and in vivo (not shown). 29 32P-labelling of other (more acidic) tryptic 30 phosphopeptides was not increased by insulin (Fig 4d). 31 These peptides have been noted previously in GSK3 from 32 A431 cells and shown to contain phosphoserine and 33 phosphotyrosine (Saito et al., 1994). 34 35

36 PKC- δ , ε and ζ are reported to be activated by

PCT/GB96/03186 WO 97/22360

18

mitogens, and PKC-7 activity is stimulated in vitro by 1 several inositol phospholipids, including PI(3,4,5)P3 2 the product of the PI 3-kinase reaction (Andjelkovic et 3 al., 1995). However, purified PKC-ε (Palmer et al., 4 1995), PKC-δ and PKC-ζ (data not shown) all failed to 5 inhibit GSK3- α or GSK3- β in vitro. Moreover, although 6 PKC- α , β 1 and γ inhibit GSK3- β in vitro (Palmer et al., 7 1995), GSK3- α is unaffected, while their downregulation 8 in L6 myotubes by prolonged incubation with phorbol 9 esters abolishes the activation of MAPKAP kinase-1 in 10 response to subsequent challenge with phorbol esters, 11 but has no effect on the inhibition of GSK3 by insulin 12 (not shown). 13 Taken together, our results identify GSK3 as a substrate for PKB. The stimulation of glycogen

14

15 16 synthesis by insulin in skeletal muscle involves the 17 dephosphorylation of Ser residues in glycogen synthase 18 that are phosphorylated by GSK3 in vitro (Parker et 19 al., 1983). Hence the 40-50% inhibition of GSK3 by 20 insulin, coupled with a similar activation of the 21 relevant glycogen synthase phosphatase (Goode et al., 22 1992), can account for the stimulation of glycogen 23 synthase by insulin in skeletal muscle (Parker et al., 24 1983) or L6 myotubes (Goode et al., 1992). 25 activation of glycogen synthase and the resulting 26 stimulation of glycogen synthesis by insulin in L6 27 myotubes is blocked by wortmannin, but not by PD 98059 28 (Dent et al., 1990), just like the activation of 29 Akt/RAC and inhibition of GSK3. However, GSK3 is 30 unlikely to be the only substrate of PKB in vivo, and 31 identifying other physiologically relevant substrates 32 will be important because PKBeta is amplified and over-33 expressed in many ovarian neoplasms (Cheng et al., 34 1992). 35

36

1	Example 2: Activation of PKB by insulin in L6 myotubes
2	is accompanied by phosphorylation of residues Thr-308
3	and Ser-473. Insulin induces the activation and
4	phosphorylation of PKBa in L6 myotubes. Three 10 cm
5	dishes of L6 myotubes were TP-labelled and treated for
6	10 min with or without 100 nM wortmannin and then for 5
7	min with or without 100 nM insulin. PKBα was
8	immunoprecipitated from the lysates and an aliquot
9	(15%) assayed for PKB α activity (Fig 5A). The
LO	activities are plotted + SEM for 3 experiments relative
11	to PKBα derived from unstimulated cells which was 10
12	mU/mg. The remaining 85% of the immunoprecipitated PKB α
13	was alkylated with 4-vinylpyridine, electrophoresed on
14	a 10% polyacrylamide gel (prepared without SDS to
15	enhance the phosphorylation-induced decrease in
16	mobility) and autoradiographed. The positions of the
17	molecular mass markers glycogen phosphorylase (97 kDa),
18	bovine serum albumin (66 kDa) and ovalbumin (43 kDa)
19 .	are marked.
20	
21	Under these conditions, insulin stimulation resulted in
22	a 12-fold activation of PKB $lpha$ (Fig 5A) and was
23	accompanied by a 1.9 ± 0.3-fold increase in
24	³² P-labelling (4 experiments) and retardation of its
25	mobility on SDS-polyacrylamide gels (Fig 5B). The
26	activation of PKBa, the increase in its 32P-labelling
27	and reduction in electrophoretic migration were all
28	abolished by prior incubation of the cells with 100 nM
29	wortmannin. Phosphoamino acid analysis of the whole
30	protein revealed that ³² P-labelled PKBα was
31	phosphorylated at both serine and threonine residues
32	and that stimulation with insulin increased both the
33	32P-labelling of both phosphoamino acids (data not
34	shown).
35	

Fig. 6. Insulin stimulation of L6 myotubes induces the

20

phosphorylation of two peptides in PKBa. 1 corresponding to 32P-labelled PKBa from Fig 5B were 2 excised from the gel, treated with 4-vinylpyridine to 3 alkylate cysteine residues, digested with trypsin and 4 chromatographed on a Vydac 218TP54 C18 column 5 (Separations Group, Hesperia, CA) equilibrated with 6 0.1% (by vol) trifluoroacetic acid (TFA), and the 7 columns developed with a linear acetonitrile gradient 8 (diagonal line). The flow rate was 0.8 ml / min and 9 fractions of 0.4 ml were collected (A) tryptic peptide 10 map of ³²P-labelled PKBα from unstimulated L6 myotubes; 11 (B) tryptic peptide map of ³²P-labelled PKBα from 12 insulin-stimulated L6 myotubes; (C) tryptic peptide map 13 of 32P-labelled PKBa from L6 myotubes treated with 14 wortmannin prior to insulin. The two major 32P-labelled 15 peptides eluting at 23.7% and 28% acetonitrile are 16 named Peptide A and Peptide B, respectively. Similar 17 results were obtained in four (A and B) and two (C) 18 experiments. 19 20 No major 32P-labelled peptides were recovered from 21 32P-labelled PKBa derived from unstimulated L6 myotubes 22 (Fig 6A) indicating that, in the absence of insulin, 23 there was a low level phosphorylation at a number of 24 sites. However, following stimulation with insulin, two 25 major 32P-labelled peptides were observed, termed A and 26 B (Fig 6B), whose 32P-labelling was prevented if the 27 myotubes were first preincubated with wortmannin (Fig 28 29 6C). 30 Fig 7. Identification of the phosphorylation sites in 31 peptides A and B. (A) Peptides A and B from Fig5B 32 (1000cpm) were incubated for 90min at 110°C in 6M HCl, 33 electrophoresed on thin layer cellulose at pH 3.5 to 34 resolve orthophosphate (Pi), phosphoserine (pS), 35 phosphthreonine (pT) and phosphotyrosine (pY) and 36

WO 97/22360

21

PCT/GB96/03186

autoradiographed. (B) Peptide A (Fig 5B) obtained from 1 50 10 cm dishes of 32P-labelled L6 myotubes was further 2 purified by chromatography on a microbore C18 column 3 equilibrated in 10 mM ammonium acetate pH 6.5 instead 4 of 0.1% TFA. A single peak of 32P-radioactivity was 5 observed at 21% acetonitrile which coincided with a 6 peak of 214 nm absorbance. 80% of the sample (1 pmol) 7 was analysed on an Applied Biosystems 476A sequencer to 8 determine the amino acid sequence, and the 9 phenylthiohydantoin (Pth) amino acids identified after 10 each cycle of Edman degradation are shown using the 11 single letter code for amino acids. The residues in 12 parentheses were not present in sufficient amounts to 13 be identified unambiguously. To identify the site(s) 14 of phosphorylation, the remaining 20% of the sample 15 (600 cpm) was then coupled covalently to a Sequelon 16 arylamine membrane and analysed on an Applied 17 Biosystems 470A sequencer using the modified programme 18 described by Stokoe et al. (1992). "P radioactivity was 19 measured after each cycle of Edman degradation. (C) 20 Peptide B from Fig 2B (800 cpm) was subjected to solid 21 phase sequencing as in (B). 22 23 Peptide A was phosphorylated predominantly on serine 24 while peptide B was labelled on threonine (Fig 7A). 25 Amino acid sequencing established that peptide A 26 commenced at residue 465. Only a single burst of 27 32P-radioactivity was observed after the eighth cycle of 28 Edman degradation (Fig 7B), demonstrating that insulin 29 stimulation of L6 myotubes had triggered the 30 phosphorylation of PKB α at Ser-473, which is located 9 31 residues from the C-terminus of the protein. 32 Phosphopeptide B was only recovered in significant 33 amounts if $^{.32}$ P-labelled PKB α was treated with 34 4-vinylpyridine prior to digestion with trypsin, 35 indicating that this peptide contained a cysteine 36

residues 308-325 of PKBa.

WO 97/22360 PCT/GB96/03186

22

residue(s), and a single burst of 32p radioactivity was 1 observed after the first cycle of Edman degradation 2 (Fig 7C). This suggested that the site of 3 phosphorylation was residue 308, since it is the only 4 threonine in PKBa that follows a lysine or arginine residue and which is located in a tryptic peptide 6 containing a cysteine residue (at position 310). The 7 acetonitrile concentration at which phosphopeptide B is 8 eluted from the C18 column (28%) and its isoelectric 9 point (4.0) are also consistent with its assignment as 10 the peptide comprising residues 308-325 of PKBa. The 11 poor recoveries of Peptide B during further 12 purification at pH 6.5 prevented the determination of 13 its amino acid sequence, but further experiments 14 described below using transiently transfected 293 cells 15 established that this peptide does correspond to 16

Fig 8: Mapping the phosphorylation sites of PKBa in transiently transfected 293 cells. 293 cells were transiently transfected with DNA constructs expressing wild type PKBα, or a haemagglutonin epitope-tagged PKBα encoding the human protein, such as HA-KD PKBa, HA-473A PKBa or HA-308A PKBa. After treatment for 10 min with or without 100 nM wortmannin, the cells were stimulated for 10 min with or without 100 nM insulin or 50 ng/ml IGF- 1 in the continued presence of wortmannin. PKBa was immunoprecipitated from the lysates and assayed, and activities corrected for the relative levels of expression of each HA-PKBa. The results are expressed relative to the specific activity of wild type HA-PKBa from unstimulated 293 cells (2.5 \pm 0.5 U/mg). (B) 20 μ g of protein from each lysate was electrophoresed on a 10 % SDS/polyacrylamide gel and immunoblotted using monoclonal HA-antibody. The molecular markers are those used in Fig 5B.

Fig 9: IGF-1 stimulation of 293 cells induces the 1 phosphorylation of two peptides in transfected HA-PKBa. 2 293 cells transiently transfected with wild type $HAPKB\alpha$ 3 DNA constructs were 32P-labelled, treated for 10 min 4 without (A,B) or with (C) 100 nM wortmannin and then 5 for 10 min without (A) or with (B, C) 50 ng/ml IGF-1. 6 The 32p labelled HA-PKBa was immunoprecipitated from 7 the lysates, treated with 4-vinylpyridine, 8 electrophoresed on a 10% polyacrylamide gel, excised 9 from the gel and digested with trypsin. Subsequent 10 chromatography on a C_{18} column resolved four major 11 phosphopeptides termed C, D, E and F. Similar results 12 were obtained in 6 separate experiments for (A) and 13 (B), and in two experiments for (C). 14 15 Stimulation with insulin and IGF-1 resulted in 20-fold 16 and 46-fold activation of transfected $PKB\alpha$, 17 respectively (Fig 8A), the half time for activation 18 being 1 min, as found with other cells. Activation of 19 $PKB\alpha$ by insulin or IGF-1 was prevented by prior 20 incubation with wortmannin (Fig 8A) and no activation 21 occurred if 293 cells were transfected with vector 22 alone and then stimulated with insulin or 1GF-1 (data 23 not shown). 24 25 Two prominent 32P-labelled peptides were present in 26 unstimulated 293 cells (Fig 9A). One, termed Peptide C, 27 usually eluted as a doublet at 20-21% acetonitrile 28 while the other, termed Peptide F, eluted at 29.7% 29 acetonitrile. Stimulation with insulin or IGF-1 did 30 not affect the 32P-labelling of Peptides C and F (Figs 31 9A & B), but induced the 32P-labelling of two new 32 peptides, termed D (23.4% acetonitrile) and E 33 (28% acetonitrile), which eluted at the same 34 acetonitrile concentrations as peptides A and B from L6 35 myotubes (Fig 6B) and had the same isoelectric points 36

24

(7.2 and 4.0, respectively). Treatment of 293 cells 1 expressing HA-PKBa with 100 nM wortmannin, prior to 2 stimulation with IGF-1, prevented the phosphorylation 3 of Peptides D and E, but had no effect on the 32p 4 labelling of Peptides C and F (Fig 9C). 5 6 Peptides C, D, E and F were further purified by re-7 chromatography on the C18 column at pH 6.5 and 8 sequenced. Peptides C gave rise to three separate (but 9 closely eluting) 32P-labelled peptides (data not shown). 10 Amino acid sequencing revealed that all three commenced 11 at residue 122 of PKBa and that Ser-124 was the site of 12 phosphorylation (Fig 10A). Peptide D only contained 13 phosphoserine and, as expected, corresponded to the 14 PKBa tryptic peptide commencing at residue 465 that was 15 phosphorylated at Ser-473 (Fig 10B). Peptide E, only 16 contained phosphothreonine and amino acid sequencing 17 demonstrated that it corresponded to residues 308-325, 18 the phosphorylation site being Thr-308 (Fig 10C). 19 Peptide F only contained phosphothreonine and 20 corresponded to the peptide commencing at residue 437 21 of PKBα phosphorylated at Thr-450 (Fig 10D). 22 23 In the presence of phosphatidylserine, PKBa binds to 24 PIP3 with submicromolar affinity (James et al., 1996, 25 Frech et al., 1996). Phosphatidyl 4,5-bisphosphate and 26 phosphatidyl 3,4 bisphosphate bind to PKBa with lower 27 affinities and PI 3,5 bisphosphate and PI 3 phosphate 28 did not bind at all under these conditions (James et 29 al., 1996). The region of PKBα that interacts with PIP3 30 is almost certainly the PH domain, because the isolated 31 PH domain binds PIP3 with similar affinity to PKB α 32 itself (Frech et al., 1996) and because the PH domain 33 of several other proteins, such as the PH-domains of, 34 β -spectrin and phospholipase Cl, are known to interact 35 specifically with other phosphoinositides (Hyvonen et 36

25

al., 1995 and Lemmon et al., 1995). 1 2 The experiments described above were repeated using 3 insulin instead of IGF-1. The results were identical, 4 except that the 32P-labelling of Peptides D and E was 5 about 50% of the levels observed with IGF-1 (data not 6 shown). This is consistent with the two-fold lower 7 level of activation of $PKB\alpha$ by insulin compared with 8 IGF-1 (Fig 7A). 9 10 Example 3: MAPKAP kinase-2 phosphorylates Ser-473 of 11 PKBα causing partial activation. Ser-473 of PKBa lies 12 in a consensus sequence Phe-x-x-Phe/Tyr-Ser/Thr-Phe/Tyr 13 found to be conserved in a number of protein kinases 14 that participate in signal transduction pathways 15 (Pearson et al. 1995). In order to identify the Ser-473 16 kinase(s) we therefore chromatographed rabbit skeletal 17 muscle extracts on CM-Sephadex, and assayed the 18 fractions for protein kinases capable of 19 phosphorylating a synthetic peptide corresponding to 20 residues 465 to 478 of PKB α . These studies identified 21 an enzyme eluting at 0.3 M NaCl which phosphorylated 22 the peptide 465-478 at the residue equivalent to 23 Ser-473 of PKBa. The Ser473 kinase co-eluted from 24 CM-Sephadex with MAP kinase-activated protein (MAPKAP) 25 kinase-2, (Stokoe et al, 1992) which is a component of 26 a stress and cytokine-activated MAP kinase cascade 27 (Rouse et al, 1994; Cuenda et al, 1995). The Ser-473 28 kinase continued to cofractionate with MAPKAPkinase-2 29 through phenyl-Sepharose, heparin-Sepharose, Mono S and 30 Mono Q and was immunoprecipitated quantitatively by an 31 anti-MAPKAP kinase-2 antibody (Gould et al, 1995) 32

36 Figure 11. HA-PKBα was immunoprecipitated from the

Ser-473 kinase we had purified.

lysates of unstimulated COS-1 cells expressing these 1 constructs. (A) 0.5 μ g of immunoprecipitated HA-PKB α 2 was incubated with MAPKAP kinase-2 (50 U/ml), 10 mM 3 magnesium acetate and 100 mM [γ^{32} P]ATP in a total of 40 4 μ l of Buffer B. At various times, aliquots were removed 5 and either assayed for PKBa activity (open circles) or 6 for incorporation of phosphate into PKBa (closed 7 circles). Before measuring PKBa activity, EDTA was 8 added to a final concentration of 20 mM to stop the 9 reaction, and the immunoprecipitates washed twice with 10 1.0 ml of buffer B containing 0.5 M NaCl, then twice 11 with 1.0 ml of Buffer B to remove MAPKAP kinase-2. The 12 results are presented as \pm SEM for six determinations 13 (two separate experiments) and $PKB\alpha$ activities are 14 presented relative to control experiments in which 15 HA-PKBα was incubated with MgATP in the absence of 16 MAPKAP kinase-2 (which caused no activation). 17 Phosphorylation was assessed by counting the 18 ³²P-radioactivity associated with the band of PKBα after 19 SDS/polyacrylamide gel electrophoresis. The open 20 triangles show the activity of immunoprecipitated HA-KD 21 PKBα phosphorylated by MAPKAP kinase-2. (B) HA-PKBα 22 phosphorylated for 1 h with MAPKAP kinase-2 and 32P-23 γ -ATP as in (A) was digested with trypsin and 24 chromatographed on a C18 column as described in the 25 legend for Fig 2. (C) The major 12P-labelled peptide 26 from (B) was analysed on the 470A sequencer as in Fig 3 27 to identify the site of phosphorylation. 28 29 Bacterially expressed MAPKAP kinase-2 phosphorylated 30 wild type $HA-PKB\alpha$ or the catalytically inactive mutant 31 $HA-PKB\alpha$ in which Lys- 179 had been mutated to Ala (data 32 not shown) to a level approaching 1 mol per mole 33 protein (Fig 11A). Phosphorylation of wild-type PKB α 34 was paralleled by a seven-fold increase in activity, 35 whereas phosphorylation of the catalytically inactive 36

PCT/GB96/03186

mutant did not cause any activation (Fig 11A). No 1 phosphorylation or activation of wild type HA-PKBa 2 occurred if MAPKAP kinase-2 or MgATP was omitted from 3 the reaction (data not shown). Wild type $HA-PKB\alpha$ that 4 had been maximally activated with MAPKAP kinase-2, was 5 completely dephosphorylated and inactivated by 6 treatment with protein phosphatase 2A (data not shown). 7 8 $HA-PKB\alpha$ that had been maximally phosphorylated with 9 MAPKAP kinase-2 was digested with trypsin and C18 10 chromatography revealed a single major 32P-labelled 11 phosphoserine-containing peptide (Fig 11B). This 12 peptide eluted at the same acetonitrile concentration 13 (Fig 11B) and had the same isoelectric point of 7.2 14 (data not shown) as the 32p labelled tryptic peptide 15 containing Ser-473 (compare Figs 11B and 6B). Solid 16 phase sequencing gave a burst of 32P-radioactivity after 17 the eighth cycle of Edman degradation (Fig 11C), 18 establishing that Ser-473 was the site of 19 phosphorylation. The same 32P-peptide was obtained 20 following tryptic digestion of catalytically inactive 21 HA-KD PKB α that had been phosphorylated with MAPKAP 22 kinase-2 (data not shown). 23 24 Example 4: Phosphorylation of Thr-308 and Ser-473 25 causes synergistic activation of PKBa. The experiments 26 described above demonstrated that phosphorylation of 27 Ser-473 activates PKBa in vitro but did not address the 28 role of phosphorylation of Thr-308, or how 29 phosphorylation of Thr-308 might influence the effect 30 of Ser-473 phosphorylation on activity, or vice versa. 31 We therefore prepared haemagglutonin (HA)-tagged PKBa 32 DNA constructs in which either Ser-473 or Thr-308 would 33 be changed either to Ala (to block the effect of 34 phosphorylation) or to Asp (to try and mimic the effect 35 of phosphorylation). 36

Fig 12. Activation of HA-PKBa mutants in vitro by 1 MAPKAP kinase-2. (A) Wild type and mutant HA-PKBa 2 proteins were immunoprecipitated from the lysates of 3 unstimulated COS-1 cells expressing these constructs 4 and incubated for 60 min with MgATP in the absence (-, 5 filled bars) or presence (+, hatched bars) of MAPKAP 6 kinase-2 and MgATP (50 U/ml). The PKBα protein was 7 expressed as similar levels in each construct and 8 specific activities are presented relative to wild type 9 HA-PKBα incubated in the absence of MAPKAP kinase-2 10 (0.03 U/mg). The results are shown as the average \pm SEM 11 for 3 experiments. (B) 20 μ g of protein from each 12 lysate was electrophoresed on a 10 % SDS/polyacrylamide 13 14 gel and immunoblotted using monoclonal HA-antibody. 15 All the mutants were expressed at a similar level in 16 serum-starved COS-1 cells (data not shown) and the 17 effects of maximally phosphorylating each of them at 18 Ser-473 is shown in Fig 12A. Before phosphorylation 19 with MAPKAP kinase-2 the activity of HA-473A PKBa was 20 similar to that of unstimulated wild type $HA-PKB\alpha$ and, 21 as expected, incubation with MAPKAP kinase-2 and MgATP 22 did not result in any further activation of HA-473A 23 In contrast, the activity of HA-473D $PKB\alpha$ was 24 five-fold to six-fold higher than that of unstimulated 25 wild type HAPKBa protein, and similar to that of 26 wild-type HA-PKBα phosphorylated at Ser-473. As 27 expected, HA-473D PKBa was also not activated further 28 by incubation with MAPKAP kinase-2 and MgATP. The 29 activity of HA-308A PKBa was about 40% that of the 30 unstimulated wild type enzyme, and after 31 phosphorylation with MAPKAP kinase-2 is activity 32 increased to a level similar to that of wild type 33 HA-PKBα phosphorylated at Ser-473. Interestingly, 34 ${\rm HA-308D~PKB}\alpha$ which (like ${\rm HA-473D~PK}$) was five-fold more 35 active than dephosphorylated wild type HA-PKBa, was 36

PCT/GB96/03186

activated dramatically by phosphorylation of Ser-473. 1 After incubation with MAPKAP kinase-2 and MgATP, the 2 activity of HA-308D PKBa was nearly five-fold higher 3 than that of wild type HA-PKBa phosphorylated at 4 Ser-473 (Fig 12B). These results suggested that the 5 phosphorylation of either Thr-308 or Ser-473 leads to 6 partial activation of PKBa in vitro, and that 7 phosphorylation of both residues results in a 8 synergistic activation of the enzyme. This idea was 9 supported by further experiments in which both Thr-308 10 and Ser-473 were changed to Asp. When this double 11 mutant was expressed in COS-1 cells it was found to 12 possess an 18-fold higher specific activity than the 13 dephosphorylated wild type protein. As expected, the 14 activity of this mutant was not increased further by 15 incubation with MAPKAP kinase-2 and MgATP (Fig 12B). 16 17 Example 5: Phosphorylation of both Thr-308 and Ser-473 18 is required for a high level of activation of PKBa in 19 vivo. 20 21 Fig 9. Effect of mutation of PKBa on its activation by 22 insulin in 293 cells. (A) 293 cells were transiently 23 transfected with DNA constructs expressing wild type 24 PKBa, HA-D473- PKB α , and HA-308D/473D-PKB α . After 25 treatment for 10 min with or without 100 nM wortmannin, 26 cells were stimulated for 10 min with or without 100 nM 27 insulin in the continued presence of wortmannin. $PKB\alpha$ 28 was immunoprecipitated from the lysates and assayed, 29 and activities corrected for the relative levels of 30 ${\tt HA-PKB}\alpha$ expression as described in the methods. The 31 results are expressed relative to the specific activity 32 of wild type HA-PKBa obtained from unstimulated 293 33 cells. (B) 20 µg of protein from each lysate was 34 electrophoresed on a 10 % SDS/polyacrylamide gel and 35 immunoblotted using monoclonal HA-antibody. 36

30

WO 97/22360 PCT/GB96/03186

The basal level of activity of HA-473A PKBa derived 1 from unstimulated cells was similar to that of wild 2 3 type PKBa (Fig 8A). Stimulation of 293 cells expressing HA-473A PKBα with insulin or IGF-1 increased the 4 activity of this mutant three-fold and five-fold 5 respectively; i.e. to 15% of the activity of wild type 6 7 HA-PKBα which had been transiently expressed and stimulated under identical conditions. The basal 8 activity of HA-308A PKBα in unstimulated cells was also 9 similar to that of wild type HA-PKBa derived from 10 unstimulated cells, but virtually no activation of this 11 mutant occurred following stimulation of the cells with 12 insulin or IGF-1. These data are consistent with in 13 vitro experiments and indicate that maximal activation 14 of PKBa requires phosphorylation of both Ser-473 and 15 Thr-308 and that phosphorylation of both residues 16 results in a synergistic activation of the enzyme. 17 Consistent with these results, HA-473D PKBa displayed 18 five-fold higher activity and the HA-308D/HA473D double 19 mutant 40-fold higher activity than wild type HA-PKBa 20 when expressed in unstimulated cells. Following 21 stimulation with insulin, HA-473D PKBa was activated to 22 a level similar to that observed with the wildtype 23 enzyme, while the HA-308D/HA-473D double mutant could 24 not be activated further (Fig 13). As expected, 25 activation of HA-473D PKB α by insulin was prevented by 26 wortmannin, and the activity of the HA-308D/ HA-473D 27 double mutant was resistant to wortmannin (Fig 13). 28 29 Example 6: Phosphorylation of Thr-308 is not dependent 30 on phosphorylation of Ser-473 or vice versa (in 293 31 cells). (Fig 10) A 10 cm dish of 293 cells were 32 transfected with either HA-308A PKBa or HA-473A PKBa, 33 32P-labelled, then stimulated for 10 min with either 34 IGF-1 (50 ng/ml) or buffer. The ^{32}P -labelled PKB α 35 mutants were immunoprecipitated from the lysates. 36

31

treated with 4-vinylpyridine, electrophoresed on a 10% 1 polyacrylamide gel, excised from the gel and digested 2 with trypsin, then chromatographed on a C18 column. 3 The tryptic peptides containing the phosphorylated 4 residues Ser-124, Thr-308, Thr-450, Ser-473 are marked 5 and their assignments were confirmed by phosphoamino 6 acid analysis and sequencing to identify the sites of 7 phosphorylation (data not shown). The phosphopeptides 8 containing Thr-308 and Ser-473 were absent if 9 stimulation with IGF-1 was omitted, while the 10 phosphopeptides containing Ser-124 and Thr-450 were 11 present at similar levels as observed with wild-type 12 PKBlpha (see Fig 9A). Similar results were obtained in 3 13 separate experiments. 14 15 These experiments demonstrated that IGF-1 stimulation 16 induced the phosphorylation of HA-473A PKB α at Thr-308, 17 and the phosphorylation of HA-308A PKB α at Ser-473. 18 Similar results were obtained after stimulation with 19 insulin rather than IGF-I. 20 21 Example 7: IGF-1 or insulin induces phosphorylation of 22 Thr-308 and Ser-473 in a catalytically inactive mutant 23 of PKBa. 24 25 Fig 15. The catalytically inactive PKBα mutant 26 (HA-KD-PKBa) expressed in 293 cells is phosphorylated 27 at Thr-308 and Ser-473 after stimulation with IGF-1. 28 Each 10 cm dish of 293 cells transiently transfected 29 with $HA-KD-PKB\alpha$ DNA constructs was ^{32}P -labelled and 30 incubated for 10 min with buffer (A), 50 ng/ml IGF-1 31 (B) or 100 nM insulin (C). The ^{32}P -labelled HA-KD-PKB α 32 was immunoprecipitated from the lysates, treated with 4 33 vinylpyridine, electrophoresed on a 10% polyacrylamide 34 gel, excised from the gel and digested with trypsin, 35 then chromatographed on a C18 column. The tryptic 36

32

peptides containing the phosphorylated residues 1 Ser-124, Thr-308, Thr-450 and Ser-473 are marked. 2 Similar results were obtained in 3 separate experiments for (A) and (B), and in two experiments for (C). 4 5 This kinase dead" mutant of PKBa, termed HA-KD-PKBa, in 6 which Lys-179 was changed to Ala (see above) was 7 transiently expressed in 293 cells and its level of 8 expression found to be several-fold lower than that of 9 wild type HA-PKBa expressed under identical conditions 10 (Fig 8B). As expected, no PKBα activity was detected 11 when 293 cells expressing HA-KD-PKBa, were stimulated 12 with insulin or IGF-1 (Fig 7A). 13 14 293 cells that had been transiently transfected with 15 HA-KD-PKBα were ³²P-labelled, then stimulated with 16 buffer, insulin or IGF-1. and sites on PKBa 17 phosphorylated under these conditions were mapped. In 18 contrast to wild type $HA-PKB\alpha$ from unstimulated 293 19 cells (Fig 9), HA-KD PKBa was phosphorylated to a much 20 lower level at Ser-124, but phosphorylated similarly at 21 Thr-450 (Fig 15A). Following stimulation with IGF-1 22 (Fig 15B) or insulin (Fig 14C) HA-KD-PKBα became 23 phosphorylated at the peptides containing Thr-308 and 24 Ser-473, the extent of phosphorylation of these sites 25 being at least as high as wild type PKBa. Amino acid 26 sequencing of these peptides established that they were 27 phosphorylated at Thr-308 and Ser-473, respectively. 28 29 The above examples establish that PKB influences GSK3 30 activity; that Thr-308 and Ser-473 are the major 31 residues in PKBa that become phosphorylated in response 32 to insulin or IGF-1 (Figs 2 and 5) and that 33 phosphorylation of both residues is required to 34 generate a high level of PKBa activity. Thus mutation 35 of either Thr-308 or Ser-473 to Ala greatly decreased 36

33

the activation of transfected PKB α by insulin or IGF-1 1 in 293 cells (Fig 8). Moreover, PKBa became partially 2 active in vitro when either Thr-308 or Ser-473 were 3 changed to Asp or when Ser-473 was phosphorylated by 4 MAPKAP kinase-2 in vitro, and far more active when the 5 D308 mutant of PKBa was phosphorylated by MAPKAP 6 kinase-2 or when Thr-308 and Ser-473 were both mutated 7 to Asp (Fig 12). Moreover, the D308/D473 double mutant 8 could not be activated further by stimulating cells 9 with insulin (Fig 13). These observations demonstrate 10 that the phosphorylation of Thr-308 and Ser-473 act 11 synergistically to generate a high level of $PKB\alpha$ 12 activity. 13 14 Thr-308, and the amino acid sequence surrounding it, is 15 conserved in rat PKB β and PKB γ but, interestingly, 16 Ser-473 (and the sequence surrounding it) is only 17 conserved in PKBeta. In rat PKB γ , Ser-473 is missing 18 because the C-terminal 23 residues are deleted. This 19 suggests that the regulation of PKB γ may differ 20 significantly from that of PKBlpha and PKBeta in the rat. 21 22 Thr-308 is located in subdomain VIII of the kinase 23 catalytic domain, nine residues upstream of the 24 conserved Ala-Pro-Glu motif, the same position as 25 activating phosphorylation sites found in many other 26 protein kinases. However, Ser-473 is located C-terminal 27 to the catalytic domain in the consensus sequence 28 Phe-Xaa-Xaa-Phe/Tyr-Ser/Thr-Phe/Tyr which is present in 29 several protein kinases that participate in growth 30 factor-stimulated kinase cascades, such as p70 S6 31 kinase, PKC and p90rsk (Pearson et al, 1995). However, 32 it is unlikely that a common protein kinase 33 phosphorylates this motif in every enzyme for the 34 following reasons. Firstly, phosphorylation of the 35 equivalent site in p70 S6 kinase is prevented by the 36

34

immunosuppressant drug rapamycin (Pearson et al, 1995) 1 which does not prevent the activation of PKBa by 2 insulin (Cross et al, 1995) or is phosphorylation at 3 Ser-473 (D. Alessi, unpublished work). Secondly, the 4 equivalent residue in protein kinase C is 5 phosphorylated constitutively and not triggered by 6 stimulation with growth factors (Tsutakawa et al., 7 8 1995). 9 MAPKAP kinase-2 is a component of a protein kinase 10 cascade which becomes activated when cells are 11 stimulated with interleukin-1 or tumour necrosis factor 12 or exposed cellular stresses (Rouse et al, 1994; Cuenda 13 et al, 1995). MAPKAP kinase-2 phosphorylates PKBa 14 stoichiometrically at Ser-473 (Fig 11) and this finding 15 was useful in establishing the role of Ser473 16 phosphorylation in regulating PKBa activity. However, 17 although MAPKAP kinase-2 activity is stimulated to a 18 small extent by insulin in L6 cells, no activation 19 could be detected in 293 cells in response to insulin 20 or IGF-1. Moreover, exposure of L6 cells or 293 cells 21 to a chemical stress (0.5 mM sodium arsenite) strongly 22 activated MAPKAP kinase-2 (D. Alessi, unpublished work) 23 as found in other cells (Rouse et al, 1994; Cuenda et 24 al, 1995), but did not activate PKBa at all. 25 Furthermore, the drug SB 203580 which is a specific 26 inhibitor of the protein kinase positioned immediately 27 upstream of MAPKAP kinase-2 (Cuenda et al, 1995), 28 prevented the activation of MAPKAP kinase-2 by arsenite 29 but had no effect on the activation of PKB α by insulin 30 or IGF-1. Finally, the activation of PKBa was prevented 31 by wortmannin (Figs 6 and 9), but wortmannin had no 32 effect on the activation of MAPKAP kinase-2 in L6 or 33 293 cells. It should also be noted that the sequence 34 surrounding Ser-473 of PKB α (HFPQFSY) does not conform 35

to the optimal consensus for phosphorylation by MAPKAP

36

35

kinase-2 which requires Arg at position n-3 and a bulky 1 hydrophobic residue at position n-5, (where n is the 2 position of the phosphorylated residue). The Km for 3 phosphorylation of the synthetic peptide comprising 4 residues 465-478 is nearly 100-fold higher than the Km 5 for the standard MAPKAP kinase-2 substrate peptide 6 (data not shown). It is therefore unlikely that MAPKAP 7 kinase-2 mediates the phosphorylation of Ser-473 in 8 vivo. 9 10 The enzyme(s) which phosphorylates Thr-308 and Ser-473 11 in vivo does not appear to be PKBlpha itself. Thus 12 incubation of the partially active Asp-308 mutant with 13 MgATP did not result in the phosphorylation of Ser-473, 14 phosphorylation of the latter residue only occurring 15 when MAPKAP kinase-2 was added (Fig 11A, Fig 12). 16 Similarly, Thr-308 did not become phosphorylated when 17 either the partially active D473 mutant or the 18 partially active Ser-473 phosphorylated form of $PKB\alpha$ 19 were incubated with MgATP. PKB α when bound to lipid 20 vesicles containing phosphatidylserine and PIP3 also 21 fails to activate upon incubation with MgATP (Alessi et 22 al, 1996) and after transfection into 293 cells, a 23 "kinase dead" mutant of $PKB\alpha$ became phosphorylated on 24 Thr-308 and Ser-473 in response to insulin or IGF-1 25 (Fig 14). Furthermore, $HA-PKB\alpha$ from either unstimulated 26 or insulin-stimulated 293 cells failed to phosphorylate 27 the synthetic C-terminal peptide comprising amino acids 28 467-480. 29 30 In unstimulated L6 myotubes, the endogenous PKB α was 31 phosphorylated at a low level at a number of sites (Fig 32 6A), but in unstimulated 293 cells the transfected 33 enzyme was heavily phosphorylated at Ser-124 and 34 Thr-450 (Fig 10). Ser-124 and Thr-450 are both followed 35 by proline residues suggesting the involvement of 36

36

PCT/GB96/03186 WO 97/22360

36 "proline-directed" protein kinases. Although, the 1 phosphorylation of Ser-124 was greatly decreased when 2 "kinase dead" PKBa was transfected into 293 cells (Fig 3 14), it would be surprising if Ser-124 is 4 phosphorylated by PKBa itself because the presence of a 5 C-terminal proline abolishes the phosphorylation of 6 synthetic peptides by PKBa (D.Alessi, unpublished 7 work). Since transfected PKBa is inactive in 8 unstimulated 293 cells (Fig 12), phosphorylation of 9 Ser-124 and Thr-450 clearly does not activate PKBa 10 directly. Ser-124 is located in the linker region 11 between the PH domain and the catalytic domain of the 12 mammalian PKBα isoforms but, unlike Thr-450, is not 13 conserved in the Drosophila homologue (Andjelkovic et 14 al, 1995). 15 16 While we do not wish to be bound by hypotheses, the 17 results described suggest that agonists which activate 18 PI 3-kinase are likely to stimulate $PKB\alpha$ activity via 19 one of the following mechanisms. Firstly, PIP3 or 20 PI3,4-bisP may activate one or more protein kinases 21 which then phosphorylate PKBa at Thr-308 and Ser-473. 22 Secondly, the formation of PIP3 may lead to the 23 recruitment of $PKB\alpha$ to the plasma membrane where it is 24 activated by a membrane-associated protein kinase(s). 25 The membrane associated Thr-308 and Ser-473 kinases 26 might themselves be activated by PIP3 and the 27 possibility that Thr-308 and/or Ser-473 are 28 phosphorylated directly by PI 3-kinase has also not 29 been excluded, because this enzyme is known to 30 phosphorylate itself (Dhand et al, 1994) and other 31 proteins (Lam et al, 1994) on serine residues. 32 33 Example 8: Molecular basis for substrate specificity of 34 PKB. PKB α has been shown to influence GSK3 activity. 35 GSK3 α and GSK3 β are phosphorylated at Ser-21 and Ser-9,

respectively, by two other insulin-stimulated protein 1 kinases, namely p70 S6 kinase and MAP kinase-activated 2 protein kinase-1 (MAPKAP-K1, also known as p90 S6 3 kinase). However, these enzymes are not rate-limiting 4 for the inhibition of GSK3 by insulin in L6 myotubes 5 because specific inhibitors of their activation 6 (rapamycin-p70 S6 kinase; PD 98059-MAPKAP kinase-1) 7 have no effect (Cross et al., 1995). 8 9 The activation of PI 3-kinase is essential for many of 10 the effects of insulin and growth factors, including 11 the stimulation of glucose transport, fatty acid 12 synthesis and DNA synthesis, protection of cells 13 against apoptosis and actin cytoskeletal rearrangements 14 (reviewed in Carpenter et al., 1996). 15 observations raise the question of whether $PKB\alpha$ 16 mediates any of these events by phosphorylating other 17 proteins. To address this issue we characterised the 18 substrate specificity requirements of $PKB\alpha$. We find 19 that the optimal consensus sequence for phosphorylation 20 by PKB α is the motif Arg-Xaa-Arg-Yaa-Zaa-Ser/Thr-Hyd, 21 where Yaa and Zaa are small amino acids (other than 22 glycine) and Hyd is a large hydrophobic residue (such 23 as Phe or Leu). We also demonstrate that $PKB\alpha$ 24 phosphorylates histone H2B (a substrate frequently used 25 to assay PKB α in vitro) at Ser-36 which lies in an Arg-26 Xaa-Arg-Xaa-Xaa-Ser-Hyd motif. These studies identified 27 a further PKBa substrate (Arg-Pro-Arg-Ala-Ala-Thr-Phe) 28 that, unlike other peptides, is not phosphorylated to a 29 significant extent by either p70 S6 kinase or MAPKAP-30 K1. 31

32 33

34 Results

35 Preparation of Protein Kinase Bα

36 In order to examine the substrate specificity of PKBα,

38

it was first necessary to obtain a kinase preparation 1 2 that was not contaminated with any other protein kinase activities. 293 cells were therefore transiently 3 transfected with a DNA construct expressing 4 haemagglutonin-tagged PKBa (HA-PKBa), stimulated with 5 IGF-1 and the HA-PKBa immunoprecipitated from the 6 7 lysates). IGF-1 stimulation resulted in a 38-fold activation of PKBa (Fig 16) and analysis of the 8 immunoprecipitates by SDS-polyacrylamide gel 9 10 electrophoresis revealed that the 60 kDa PKBα was the major protein staining with Coomassie Blue apart from 11 the heavy and light chains of the haemagglutonin 12 monoclonal antibody (Fig 16, Lanes 2 and 3). The minor 13 contaminants were present in control immunoprecipitates 14 15 derived from 293 cells transfected with an empty pCMV5 vector but lacked HA-PKB activity (Fig 16, Lane 4). 16 Furthermore, a catalytically inactive mutant HA-17 PKBα immunoprecipitated from the lysates of IGF-1 18 stimulated 293 cells had no Crosstide kinase activity 19 (Alessi et al., 1996). Thus, all the Crosstide activity 20 in HA-PKB immunoprecipitates is catalysed by PKBa. 21 22 23 Identification of the residues in histone H2B phosphorylated by PKBa. Currently, three substrates are 24 25 used to assay PKBa activity in different laboratories, 26 histone H2B, MBP and Crosstide. PKBα phosphorylated Crosstide with a Km of 4 μ M and a Vmax of 260 U/mg 27 (Table 7.1 A, peptide 1), histone H2B with a Km of 5 μ M 28 and a Vmax of 68 U/mg, and MBP with a Km of 5 μ M and a 29 Vmax of 25 U/mg. Thus the Vmax of histone H2B and MBP 30 are 4-fold and 10-fold lower than for Crosstide. 31 order to identify the residue(s) in histone H2B 32 phosphorylated by PKBa, 12P-labelled histone H2B was 33 digested with trypsin (see Methods) and the resulting 34 peptides chromatographed on a C18 column at pH 1.9. 35

Only one major 12P-labelled peptide (termed T1) eluting

39 at 19.5 % acetonitrile was observed (Fig 17A), The 1 peptide contained phosphoserine (data not shown), its 2 sequence commenced at residue 34 of histone H2B and a 3 single burst of radioactivity occurred after the third 4 cycle of Edman degradation (Fig 17B), demonstrating 5 that PKBa phosphorylates histone H2B at Ser-36 within 6 the sequence Arg-Ser-Arg-Lys-Glu-Ser-Tyr. Thus, like 7 the serine phosphorylated in Crosstide, Ser-36 of 8 histone H2B lies in an Arg-Xaa-Arg-Xaa-Xaa-Ser-Hyd 9 motif (where Hyd is a bulky hydrophobic residue -Phe in 10 Crosstide, Tyr in H2B). 11 12 Molecular basis for the substrate specificity of PKBa 13 To further characterise the substrate specificity 14 requirements for $PKB\alpha$, we first determined the minimum 15 sequence phosphorylated efficiently by PKBa by removing 16 residues sequently from the C-terminal and N-terminal 17 end of Crosstide. Removal of the N-terminal glycine and 18 up to three residues from the C-terminus had little 19 effect on the kinetics of phosphorylation by PKBa 20 (Table 7.1A, compare peptides 1 and 5). However any 21 further truncation of either the N or C-terminus 22 virtually abolished phosphorylation (Table 7.1A, 23 peptides 8 and 9). The minimum peptide phosphorylated 24 efficiently by PKBa (Arg-Pro-Arg-Thr-Ser-Ser-Phe) was 25 found to be phosphorylated exclusively at the second 26 serine residue as expected. Consistent with this 27 finding, a peptide in which this serine was changed to 28 alanine was not phosphorylated by PKBa (Table 7.1A, 29 peptide 7). All further studies were therefore carried 30

32 below).

31

A peptide in which the second serine of peptide 5

35 (Table 7.1A) was replaced by threonine was

36 phosphorylated with a Km of 30 μ M and an unchanged Vmax

out using variants of peptide 5 in Table 7.1A (see

WO 97/22360

(Table 7.1, peptide 6). All the ⁿP-radioactivity 1 incorporated was present as phosphothreonine and solid 2 phase sequencing revealed that the peptide was only 3 phosphorylated at the second threonine residue, as 4 5 expected (data not shown). Thus PKBa is capable of phosphorylating threonine as well as serine residues, 6 7 but has a preference for serine. 8 9 We next changed either of the two arginine residues in peptide 5 to lysine. These substitutions drastically 10 decreased the rate of phosphorylation by PKBa (Table 11 7.1A, peptides 10 and 11) demonstrating a requirement 12 for arginine (and not simply any basic residue) at both 13 positions. 14 15 We then examined the effect of substituting the 16 residues situated immediately C-terminal to the 17 phosphorylated serine in peptide 5 (Table 7.1B). The 18 data clearly demonstrate that the presence of a large 19 hydrophobic residue at this position is critical for 20 efficient phosphorylation, with the Km increasing 21 progressively with decreasing hydrophobicity of the 22 residue at this position (Table 7.1B, peptides 1 to 4). 23 Replacement of the C-terminal residue with Lys 24 increased the Km 18-fold and a substitution at this 25 position with either Glu or Pro almost abolished 26 phosphorylation (Table 7.1B, peptides 5-7). 27 28 Replacement of the Thr situated two residues N-terminal 29 to the phosphorylated serine increased the Km with any 30 amino acid tested (Table 7.1C). Substitution with Ala 31 only increased Km by 2-3 fold, but substitution with 32 other residues was more deleterious and with Asn (a 33 residue of similar size and hydrophilicity to Thr) 34 phosphorylation was almost abolished (Table 7.1C). 35 Replacement of the Ser situated one residue N-terminal 36

40

PCT/GB96/03186

WO 97/22360

41

PCT/GB96/03186

to the phosphorylated serine also increased the Km with 1 any amino acid tested, but the effects were less severe 2 than at position n-2 (Table 7.1C). When residues n-23 and n-1 were both changed to Ala, the resulting peptide 4 RPRAASF was phosphorylated by PKBα with a Km only 5-5 fold higher than RPRTSSF. In contrast the peptides 6 RPRGGSF, RPRAGSF, and RPRGASF were phosphorylated less 7 efficiently (Table 7.1C). 8 9 Comparison of the substrate specificity of PKBa with 10 MAPKAP kinase-1, and p70 S6 kinase. Since MAPKAP-K1 11 and p70 S6 kinase phosphorylate the same residue in 12 GSK3 phosphorylated by $PKB\alpha$, and studies with synthetic 13 peptides have established that MAPKAP-K1 and p70 S6 14 kinase also preferentially phosphorylate peptides in 15 which basic residues are present at positions n-3 and 16 n-5 (Leighton et al., 1995), we compared the 17 specificities of MAPKAP-K1, p70 S6 kinase and PKB α in 18 greater detail. 19 20 MAPKAP kinase-1 and p70 S6 kinase phosphorylate the 21 peptides KKKNRTLSVA and KKRNRTLSVA with extremely low 22 Km values of 0.2-3.3 μ M, respectively (Table 7.2). 23 However, these peptides were phosphorylated by $PKB\alpha$ 24 with 50-900 fold higher Km values (Table 7.2A, peptides 25 1 and 2). The peptide KKRNRTLTV, which is a relatively 26 specific substrate for p70 S6 kinase (Leighton et al., 27 1995) was also phosphorylated very poorly by $PKB\alpha$ 28 (Table 7.2A, peptide 4). 29 30 Crosstide is phosphorylated by p70 S6 kinase and MAPKAP 31 kinase-1 with similar efficiency to PKB α ((Leighton et 32 al., 1995); Table 7.2B-peptide 1 and Fig 18). However, 33 truncation of Crosstide to generate the peptide RPRTSSF 34 was deleterious for phosphorylation by MAPKAP-K1 and 35 even worse for p70 S6 kinase (Table 7.2B-peptides 1 and 36

1 2 and Fig 18). Moreover, changing the phosphorylated

- 2 serine in RPRTSSF to threonine increased the Km for
- 3 phosphorylation by p70 S6 kinase much more than for
- 4 PKBα and almost abolished phosphorylation by MAPKAP-K1

42

PCT/GB96/03186

- 5 (Table 7.2B-peptide 3 and Fig 18). The peptide RPRAASF
- 6 was phosphorylated by MAPKAP-K1 with essentially
- 7 identical kinetics to that of PKBa; however
- 8 phosphorylation by p70 S6 kinase was virtually
- 9 abolished (Table 7.2B-peptide 4 and Fig 18). Based on
- these observations we synthesized the peptide RPRAATF.
- 11 This peptide was phosphorylated by PKBα with a Km of
- 12 25µM and similar Vmax to RPRTSSF, but was not
- phosphorylated to a significant extent by either
- 14 MAPKAP-K1 or p70 S6 kinase (Table 7.2B-peptide 5, Fig
- 15 18). In Fig 18, the protein kinase concentration in
- the assays towards Crosstide were 0.2 U/ml, and each
- peptide substrate was assayed at a concentration of 30
- 18 µM. Filled bars denote PKBa activity, hatched bars
- 19 MAPKAP kinase-1 activity, and grey bars p70 S6 kinase
- 20 activity. The activities of each protein kinase are
- given relative to their activity towards Crosstide
- 22 (100). The results are shown \pm SEM for two experiments
- 23 each carried out in triplicate.

24 25

Discussion.

WO 97/22360

- We have established that the minimum consensus sequence
- 27 for efficient phosphorylation by PKBα is Arg-Xaa-Arg-
- Yaa-Zaa-Ser-Hyd, where Xaa is any amino acid, Yaa and
- Zaa are small amino acid other than glycine (Ser, Thr,
- 30 Ala) and Hyd is a bulky hydrophobic residue (Phe, Leu)
- 31 (Table 7.1). The heptapeptide with the lowest Km value
- was RPRTSSF, its Km of 5 μ M being comparable to many of
- 33 the best peptide substrates identified for other
- protein kinases. The Vmax for this peptide (250 nmoles
- min-1 mg-1) may be an underestimate because the PKBa
- 36 was obtained by immunoprecipitation from extracts of

43

IGF-1 stimulated 293 cells over-expressing this protein kinase, and a significant proportion of the PKBα may not have been activated by IGF-1 treatment.

4

The requirement for arginine residues at positions n-3 5 (where n is the site of phosphorylation) seems 6 important, because substituting either residue with 7 lysine decreases phosphorylation drastically. 8 and threonine residues were preferred at positions n-1 9 and n-2, although the Km value was only increased about 10 5-fold if both of these residues were changed to Ala. 11 Serine was preferred at position n, since changing it 12 to threonine caused a six-fold increase in the Km. 13 The peptide RPRAATF, which was phosphorylated with a Km 14 of 25 μM and similar Vmax to RPRTSSF, may therefore be 15 a better substrate for assaying $PKB\alpha$ in partially 16 purified preparations, because unlike Crosstide, it 17 contains only one phosphorylatable residue and is not 18 phosphorylated significantly by MAPKAP-K1 or p70 S6 19 kinase (Table 7.2, Fig 18 and see below). 20

21

The Proline at position n-4 was not altered in this 22 study because it was already clear that this residue 23 was not critical for the specificity of PKBa. Residue 24 n-4 is proline in GSK3eta but alanine in GSK3lpha. Both GSK3 25 isoforms are equally good substrates for PKB α in vitro 26 (Cross et al., 1995), and the peptide 27 GRARTSSFA (corresponding to the sequence in $GSK3\alpha$) is 28 phosphorylated by PKBlpha with a Km of 10 μ M and Vmax of 29 230 U/mg (Table 7.1A, peptide 2). Moreover, in histone 30 H2B, the residue located four amino acids N-terminal to 31 the PKB α phosphorylation site is serine (Fig 17). 32 presence of Glu and Lys at positions n-1 and n-2 may 33 explain why histone H2B is phosphorylated by PKB α with 34 a four-fold lower Vmax than the peptide RPRTSSF. 35

Two other protein kinases which are activated by 1 insulin and other growth factors, p70 S6 kinase and 2 MAPKAP-K1, require basic residues at positions n-3 and 3 n-5 (Leighton et al., 1995), explaining why they also 4 phosphorylate and inactivate GSK3 in vitro (Sutherland 5 et al., 1993). Indeed, there is evidence that MAPKAP-6 K1 plays a role in the inhibition of GSK3 by EGF 7 because, unlike inhibition by insulin which is 8 prevented by inhibitors of PI 3-kinase, the inhibition 9 of GSK3 by EGF is only suppressed partially by 10 inhibitors of PI 3-kinase. Moreover, in NIH 3T3 cells, 11 the inhibition of GSK3lpha and GSK3eta by EGF is largely 12 prevented by expression of a dominant negative mutant 13 of MAP kinase kinase-1 (Eldar et al., 1995). In 14 contrast, p70 S6 kinase is not rate limiting for the 15 inhibition of GSK3 in the cells that have been examined 16 so far because rapamycin, which prevents the activation 17 of p70 S6 kinase by EGF or insulin, has no effect on 18 the inhibition of GSK3 by these agonists (Cross et al., 19 1995 and Saito et al., 1994). 20 21 Additional similarities between p70 S6 kinase, MAPKAP-22 K1 and PKBα include the failure to phosphorylate 23 peptides containing Pro at position n+1 and dislike of 24 a lysine at the same position. This suggests that, in 25 vivo, these kinases are unlikely to phosphorylate the 26 same residues as MAP kinases (which phosphorylates 27 Ser/Thr-Pro motifs) or protein kinase C (which prefers 28 basic residues C-terminal to the site of 29 However, the present work has also phosphorylation). 30 revealed significant differences in the specificities 31 of these enzymes. In particular MAPKAP-K1 and (to a 32 lesser extent) p70 S6 kinase can tolerate substitution 33 of the Arg at position n-5 by lysine whereas $PKB\alpha$ 34 cannot (see Table 7.1A, Table 7.2A and (Leighton et 35 al., 1995)). MAPKAP-K1 and p70 S6 kinase can also 36

45

tolerate, to some extent, substitution of Arg at 1 For example, the peptide position n-3 by Lys. 2 KKRNKTLSVA is phosphorylated by MAPKAP-K1 and p70 S6 3 kinase with $\,$ Km values of 17 and 34 $\,\mu$ M, respectively, 4 as compared to Km values of 0.7 and 1.5 μM for the 5 peptide KKRNRTLSVA (Table 7.2A). In contrast, $PKB\alpha$ 6 does not phosphorylate the peptide KKRNKTLSVA (Table 7 7.2A) or any other peptide that lacks Arg at position 8 n-3. PKB α and p70 S6 kinase, but not MAPKAP-K1, 9 phosphorylate Thr as well as Ser (Table 7.1A) and can 10 phosphorylate peptides lacking any residue at position 11 n+2 ((Leighton et al., 1995) and Table 7.2A), while 12 PKB α and MAPKAP-K1, but not p70 S6 kinase, can tolerate 13 substitution of both the n-1 and n-2 positions of the 14 peptide RPRTSSF with Ala (Table 7.2B). 15 differences explain why the peptide RPRAATF is a 16 relatively specific substrate for PKBa. 17 18 One of the best peptide substrates for MAPKAP-K1 and 19 p70 S6 kinase (KKRNRTLSVA) was a poor substrate for 20 PKB α (Table 7.2, peptide 2), despite the presence of 21 Arg at positions n-3 and n-5. The presence of Leu at 22 position n-1 and Val at position n+1 are likely to 23 explain the high Km for phosphorylation, because PKBlpha24 prefers a small hydrophilic residue at the former 25 position and a larger hydrophobic residue at the latter 26 position (Tables 7.1 and 7.2). 27 28 29 Example 9: This example demonstrates that coexpression of GSK3 in 30 293 cells with either the wild type or a constitutively 31 activated PKB results in GSK3 becoming phosphorylated 32 - and inactivated. However coexpression of a mutant of 33 GSK3 in which Ser-9 is mutated to an Ala residue is not 34 inactivated under these conditions. These experiments 35 provide further evidence that PKBa activation can 36

46

mediate the phosphorylation and inactivation of GSK3 in 1 a cellular environment, and could be used as an assay 2 system to search for specific PKB inhibitors. 3 Monoclonal antibodies recognising the sequence EFMPME 5 (EE) antibodies and the (EQKLISEEDL) c-Myc purchased 6 from Boehringer (Lewis, UK). 7 8 Construction of expression vectors and transfections 9 into 293 cells. HA-PKBa, HA-KD-PKB and 308D/473D 10 HA-PKBa was described previously (Alessi et al.. 1996). 11 12 A DNA construct expressing human GSK3B with the EFMPME 13 (EE) epitope tag at the N-terminus was prepared as 14 follows: A standard PCR reaction was carried out using 15 as a template the human GSK3eta cDNA clone in the 16 pBluescript SK+ vector and the oligonucleotides 17 18 GCGG<u>AGATCT</u>GCCACCATGGAGTTCATGCCCATGGAGTCAGGGCGGCCCAGAACC 19 20 and GCGGTCCGGAACATAGTCCAGCACCAG that incorporate a bql 21 II site (underlined) and a Bspe I site (double 22 underlined). A three-way ligation was then set up in 23 which the resulting PCR product was subcloned as a Bgl 24 II-Bspe I fragment together with the C-terminal Bspe 25 I-Cla I fragment of GSK3eta into the Bgl II-Cla I sites 26 of the pCMV5 vector (Anderson et al., 1989). The 27 construct was verified by DNA sequencing and purified 28 using the Quiagen plasmid Mega kit according to the 29 manufacturers protocol. The c-Myc GSK3, BA9 construct 30 encodes GSK3eta in which Ser-9 is mutated to Ala and 31

prepared as described in Sperber et al., 1995. The c-Myc GSK3 β A9 gene was then subcloned into xba I/ECOR

32 ·

35 36 possesses a c-myc epitope tag at the C-terminus and was

I sites of the pCMV5 eukaryotic expression vector.

Cotransfection of GSK3β with PKBa in 293 cells results
in GSK3 phosphorylation and inactivation

Human embryonic kidney 293 cells were transfected with
a DNA construct expressing EE-epitope tagged GSK3β
either in the presence or absence of DNA constructs
expressing wild type-PKBa, a catalytically inactive

PKBa or a constitutively active HA-(308D/473D)-PKBa. 1 Cells were serum starved for 16 h. 36h post 2 transfection the cells were lysed, and the GSK3eta3 immunoprecipitated from the lysates using monoclonal EE 4 antibodies and the GSK3 β activity measured before and 5 after treatment with PP2A. When EEGSK3eta was expressed 6 alone or in the presence of a catalytically inactive 7 PKBa, treatment of the EE-GSK3 β with PP2A only resulted 8 in about a 12% increase in activity (Fig 19A). However 9 when EE-GSK3 β was coexpressed with either the wild type 10 PKBa or the constitutively activated 308D/473D-HA-PKBa, 11 treatment of the EE-GSK3 from these cell lysates with 12 PP2A resulted in a 68% and 85% increase in the GSK3 13 activity, respectively. Coexpression of Myc-GSK3 β A9 14 with HA-PKB or the constitutively active 15 308D/473D-HA-PKBa did not result in any significant 16 inactivation of this mutant of GSK3 as judged by its 17 ability to be reactivated by PP2A (Fig 19B). These data 18 demonstrate that even in a cellular environment, PKBa 19 is capable of phosphorylating GSK3eta at Ser-9 and 20 inactivation of the enzyme. To estimate the relative 21 levels of EE-GSK3eta and PKBa, EE-GSK3 and HA-PKBa were 22 immunoprecipitated from equal volumes of cell lysate, 23 and the immunoprecipitates run on an SDS-polyacrylamide 24 gel, and the gel stained with Coomassie Blue. These 25 experiments revealed that both the wild type HA-PKBa 26 and the 308D/473D-PKBa were expressed at a 20 to 30 27 -fold higher level than GSK3a, whereas KD-PKBa is 28 expressed at a level that is about 5-fold lower than 29 that of the wild type PKBa. Under the conditions used 30 for the immunoprecipitations, no PKBa was 31 co-immnuoprecipitated with GSK3eta, or no GSK3eta was 32 co-immunoprecipitated with the PKBa (data not shown). 33 Coexpression of EE-GSK3eta with all forms of PKBa 34 resulted in about a 2-3 fold decrease in the level of 35 expression on EE-GSK3eta compared to when it is expressed 36

49

36

alone in cells. 1 2 Example 10: basic assay for identifying agents which 3 affect the activity of PKB. 4 A 40 μ l assay mix was prepared containing protein 5 kinase (0.2U/ml) in 50 mM Tris/HCI pH 7.5, 0.1 mM EGTA, 6 0.1% (by vol) 2-mercaptoethanol, 2.5 μ M PKI, protein 7 kinase substrate (30 μ M), and the indicated 8 concentration of Ro-318220 or GC 109203X (test 9 inhibitors). After incubation on ice for 10 min the 10 reaction was started by the addition of 10 μ l of 50mM 11 magnesium acetate and 0.5 mM $[\gamma^{32}P]$ ATP (100-200 12 cpm/pmol). For the assay of mixed isoforms of PKC 20 13 μM diacylglycerol, 0.5 mM CaCl₂, and 100 μM 14 phosphatidylserine were also present in the 15 incubations. The assays were carried out for 15 min at 16 30°C, then terminated and analysed as described (Alessi 17 1995). One unit of activity was that amount of enzyme 18 that catalysed the phosphorylation of 1nmol os 19 substrate in 1 min. The final concentration of DMSo in 20 each assay was 1% (by vol). This concentration of DMSO 21 does not inhibit any of these enzymes. Mixed isoforms 22 of PKC were assayed using histone H1 as substrate, 23 while MAPKAP-K1eta and p70 S6 kinase were assayed using 24 the peptide KKRNRTLSVA (Leighton 1995). Protein kinase 25 B was assayed with the peptide GRPRTSSFAEG [9] and 26 MAPKAP-K2 was assayed with the peptide KKLNRTLSVA 27 (Stokoe 1993). p42 MAP kinase was assayed using MBP, 28 and MAPKK-1, and c-Raf1 were assayed as described in 29 Alessi 1995. 30 31 Results 32 Effect of Ro 318220 and GF 109203X on protein kinases 33 activated by growth factors, cytokines and cellular 34 stresses. The mixed isoforms of PKC were potently 35 inhibited by Ro 318220, with an IC_{50} of 5 nM in our

50

assay (Fig 20A). In contrast, a number of protein 1 kinases activated by growth factors (c-Rafl, MAPKK-1, 2 p42 MAP kinase) and one protein kinase that is 3 activated by cellular stresses and proinflammatory 4 cytokines (MAPKAP-K2) were not inhibited significantly 5 by Ro 318022 in vitro (Fig 20A). Protein kinase B, an 6 enzyme that is activated in response to insulin and 7 growth factors was inhibited by Ro 318220 (IC₁₀ of 1 μ M, 8 Fig 20B) similar to the ICm for PKA. However, to our 9 surprise, MAPKAP-K1B an enzyme which lies immediately 10 downstream of p42 and p44 MAP kinases and which is 11 activated in response to every agonist that stimulates 12 this pathway, was inhibited by Ro 318220 even more **13** . potently than the mixed PKC isoforms (IC₅₀ = 3nm, Fig 14 20B). The p70 S6 kinase, which lies on a distinct 15 growth factor-stimulated signalling pathway from 16 MAPKAP-K1B, was also potently inhibited by Ro 318220 17 (IC₅₀=15 nM, Fig 20B). 18 19 Similar results were obtained using GF 109203X instead 20 of Ro 3318220. As reported previously (Toullec et al., 21 1991), GC 109203X inhibited the mixed isoforms of PKC 22 (IC_{so}=30 nM) without inhibiting protein kinase B (Fig 23 21) or c-Raf, MAPKK-1 and p42 MAP kinase (data not 24 shown). However MAPKAP-K1B and p70 S6 kinase were 25 potently inhibited by this compound with ICso values of 26 50 nM and 100 nM, respectively (Fig 21). 27

WO 97/22360 PCT/GB96/03186

General Materials and Methods Tissue culture reagents, myelin basic protein (MBP), microcystin-LR, and IGF-1 were obtained from Life Technologies Inc. (Paisley, UK), insulin from Novo-Nordisk (Bagsvaerd, Denmark), phosphate free Dulbecco's minimal essential medium (DMEM) from (ICN, Oxon, UK), Protein G-Sepharose and CH-Sepharose from Pharmacia (Milton Keynes, UK), alkylated trypsin from Promega (Southampton, UK), 4-vinylpyridine, wortmannin and fluroisothiocyanante-labelled antimouse IgG from goat from Sigma-Aldrich (Poole, Dorset, UK). Polyclonal antibodies were raised in sheep against the peptides RPHFPQFSYSASGTA (corresponding to the last 15 residues of rodent $PKB\alpha$) and MTSALATMRVDYEQIK (corresponding to residues 352 to 367 of human MAPKAPkinase-2) and affinity purified on peptide-CH-Sepharose. Monoclonal HA antibodies were purified from the tissue culture medium of 12CA5 hybridoma and purified by chromatography on Protein GSepharose. The peptide RPRHFPQFSYSAS, corresponding to residues 465-478 of $PKB\alpha$, was synthesized on an Applied Biosystems 430A peptide synthesizer. cDNA encoding residues 46-400 of human MAPKAP kinase-2 was expressed in E.coli as a glutathione S-transferase fusion protein and activated with p38/RK MAP KINASE by Mr A.Clifton (University of Dundee) as described previously (Ben-Levy et al., 1995).

Monoclonal antibodies recognising the haemagglutonin (HA) epitope sequence YPYDVPDYA, Protein G-Sepharose and histone H2B were obtained from Boehringer (Lewes, UK). MAPKAP kinase-1 (Sutherland et al., 1993) and p70 S6 kinases (Leighton et al., 1995) were purified from rabbit skeletal muscle and rat liver respectively.

Construction of expression vectors. The pECE constructs encoding the human HAPKB\$\alpha\$ and kinase-dead (K179A) HA-KD-PKB\$\alpha\$ have already been described (Andjelkovic at al., 1996). The mutants at Ser-473 (HA-473A PKB\$\alpha\$ and HA-473D PKB\$\alpha\$ were created by PCR using a 5' oligonucleotide encoding amino acids 406 - 414 and mutating 3' oligonucleotide encoding amino acids 468 - 480, and the resulting PCR products subcloned as \$CelII-EcoRI\$ fragment into pECE.HA-PKB\$\alpha\$. The Thr-308 mutants (HA-308A PKB\$\alpha\$ and HA308D PKB\$\alpha\$) were created by the two-stage PCR technique (No et al., 1989) and subcloned as \$NotI-EcoRI\$ fragments into pECE.HA-PKB\$. The double mutant HA-308D/473D PKB\$ was made by subcloning the CelII-EcoRI\$ fragment encoding 473D into pECE.HA-308D PKB\$\alpha\$. For construction of cytomegalovirus-driven expression constructs, \$BglII-XbaI\$ fragments from the appropriate pECE constructs were subcloned into the same restriction sites of the pCMV5 vector (Andersson et al., 1989).

All constructs were confirmed by restriction analysis and sequencing and purified using Quiagen Plasmid Maxi Kit according to the manufacturer's protocol. All oligonucleotide sequences are available upon request.

³²P-labelling of L6 myotubes and immunoprecipitation of PKBα. L6 cells were differentiated into myotubes on 10 cm diameter dishes (Hundal et al., 1992). The myotubes were deprived of serum overnight in DMEM, washed three times in phosphate free DMEM and incubated for a further 1 h with 5 ml of this medium. The myotubes were then washed twice with phosphate free DMEM and incubated for 4 h with carrier-free [32P]orthophosphate (1 mCi/ml). Following incubation in the presence or absence of 100 nM wortmannin for 10 min, the myotubes were stimulated for 5 min at 37°c in the presence or absence of 100 nM insulin and placed on ice, The medium was aspirated, the myotubes washed twice with ice-cold DMEM buffer and then lysed with 1.0 ml of ice-cold Buffer A (50 mM Tris/HCl pH 7.5,1 mM EDTA 1 mM EGTA, 1% (by vol) Triton X100, 1 mM sodium orthopervanadate, 10 mM sodium glycerophosphate, 50 mM NaF, 5 mM sodium pyrophosphate, 1 µM Microcystin-LR, 0.27 M sucrose, 1 mM benzamidine, 0.2 mM phenylmethylsulphonyl fluoride, 10 μ g/ml leupeptin, and 0.1% (by vol) 2-mercaptoethanol). The lysates were centrifuged at 4°C for 10 min at 13,000 x g and the supernatants incubated for 30 min on a shaking platform with 50 µl of Protein G-Sepharose coupled to 50 µg of preimmune sheep IgG. The suspensions were centrifuged for 2 min at 13,000 x g and the supernatants incubated for 60 min with 30 µl of Protein G--Sepharose covalently coupled to 60 μg of PKB α antibody (Harlow and Lane, 1988). The Protein G-Sepharose-antibody-PKBa complex was washed eight times with 1.0 ml of Buffer A containing 0.5 M NaCl, and twice with 50 mM Tris/HCl pH 7.5, 0.1 mM EGTA and 0.1% (by vol) 2-mercaptoethanol (Buffer B).

Assay of immunoprecipitated PKBa and protein determinations. Three aliquots of each immunoprecipitate (each comprising only 5% of the total immunoprecipitated PKBa) were assayed for PKBa activity towards the peptide GRPRTSSFAEG as described previously (Cross et al., 1995). One unit of activity was that amount which catalysed the phosphorylation of 1 nmol of substrate in 1 min. Protein concentrations were determined by the method of Bradford, 1976.

40 41 42

43

Tryptic digestion of in vivo phosphorylated PKBα. The immunoprecipitated PKBα was added to an equal volume of 2% (by

mass) SDS and 2 % (by vol) 2-mercaptoethanol, and incubated for 5 min at 100°C, After cooling to room temperature, 4-vinylpyridine was added to a final concentration of 2 % (by vol) and the mixture was incubated for 1h at 30°C on a shaking platform, followed by electrophoresis on a 10% polyacrylamide gel. After autoradiography, the 60 kDa band corresponding to rat PKBa was excised and the gel piece homogenized in five vols of 25 mM N-ethylmorpholine HCl, pH 7.7, containing 0.1% (by mass) SDS and 5 % (by vol) 2-mercaptoethanol. The suspension was incubated for 1 h at 37°C on a shaking platform, then centrifuged for 1 min at 13,000 x g and the supernatant collected. The pellet was incubated for a further 1h with five vols of the same buffer and centrifuged for 1min at 13,000 xg. The two supernatants (containing 80-90% of the 32P-radioactivity) were combined, 0.2 vols of 100% (by mass) trichloroacetic acid added, and the sample incubated for 1 h on ice. The suspension was centrifuged for 10 min at $13,000 \times g$, the supernatant discarded and the pellet washed five times with 0.2 ml of water. The pellet was then incubated at 30°C with 0.3 ml of 50 mM Tris/HCl pH 8.0, 0.1% (by vol) Triton X100 containing $1\mu g$ of alkylated trypsin. After 3 h another $1\mu g$ of trypsin was added and the suspension left for a further 12 h. Guanidinium hydrochloride (8 M) was added to bring the final concentration to 1.0 M in order to precipitate any residual SDS and, after standing on ice for 10 min, the suspension was centrifuged for 5 min at 13, 000 \times g. The supernatant containing 90 % of the 32P-radioactivity was chromatographed on a Vydac C18 column as described in the legend to Fig 2.

Transfection of 293 cells and immunoprecipitation of HA-tagged PKB α . Human embryonic kidney 293 cells were cultured at 37°C in an atmosphere of 5% CO2, on 10 cm diameter dishes in DMEM containing 10% foetal calf serum. Cells were split to a density of 2 x 106 per 10 cm dish, and after 24 h at 37°C the medium was aspirated and 10 ml of freshly prepared DMEM containing 10% foetal calf serum added. Cells were transfected by a modified calcium phosphate method (Chen and Okayama, 1988) with lug/ml DNA per plate. 10 μ g of plasmid DNA in 0.45 ml of sterile water was added to 50 μ l of sterile 2.5 M CaCl2, and then 0.5 ml of a sterile buffer composed of 50 mM N,N-bis[2-hydroxyethyl]-2-aminoethanesulphonic acid/HCl pH 6.96, 0.28 M NaCl and 1.5 mM Na2HPO4 was added. The resulting mixture was vortexed for 1 min, allowed to stand at room temperature for 20 min, and then added dropwise to a 10 cm dish of 293 cells). The cells were placed in

WO 97/22360 PCT/GB96/03186

an atmosphere of 3% CO2, for 16 h at 37°C, then the medium was aspirated, and replaced with fresh DMEM containing 10% foetal calf serum. The cells were incubated for 12 h at 37°C in an atmosphere of 5% CO2,, and then for 12 h in DMEM in the absence of serum. Cells were preincubated for 10 min in the presence of 0.1% DMSO or 100 nM wortmannin in 0.1% DMSO and then stimulated for 10 min with either 100 nM insulin or 50 ng/ml IGF-1 in the continued presence of wortmannin. After washing twice with ice cold DMEM the cells were lysed in 1.0 ml of icecold Buffer A, the lysate was centrifuged at 4°C for 10 min at 13,000 x g and an aliquot of the supernatant (10 μ g protein) was incubated for 60 min on a shaking platform with 5 μ l of protein G-Sepharose coupled to 2 μ g of HA monoclonal antibody. The suspension was centrifuged for 1 min at 13,000 x g, the Protein G-Sepharose-antibody-HA-PKBa complex washed twice with 1.0 ml of Buffer A containing 0.5 M NaCl, and twice with Buffer B, and the immunoprecipitate assayed for PKBlphaactivity as described above.

¹³P-Labelling of 293 cells transfected with HA-PKBα. 293 cells transfected with HA-PKBα DNA constructs. were washed with phosphate free DMEM, incubated with [32p] orthophosphate (1 mCi/ml) as described for L6 myotubes, then stimulated with insulin or IGF1 and lysed, and PKBα immunoprecipitated as described above. The ¹³P-labelled HA-PKBα immunoprecipitates were washed, alkylated with 4-vinylpyridine, electrophoresed and digested with trypsin as described above for the endogenous PKBα present in rat L6 myotubes.

Transfection of COS-1 cells and immunoprecipitation of HA-PKBα. COS-1 cells were maintained in DMEM supplemented with 10% FCS at 370C in an atmosphere of 5% CO2. Cells at 70 - 80% confluency were transfected by a DEAE-dextran method (Seed & Aruffo, 1987), and 48 hours later serum-starved for 24 hours. Cells were lysed in a buffer containing 50 mM Tris-HCl, pH 7.5,120 mM NaCl, 1% Nonidet P-40, 25 mM NaF, 40 mM sodium-,β-glycerophosphate, 0.1 mM sodium orthopervanadate, 1 mM EDTA, 1mM benzamidine, 1 mM phenylmethylsulphonyl fluoride, and lysates centrifuged for 15 min at 13,000 x g at 4°C. Supernatants were pre cleared once for 30 min at 4°C with 0.1 vols of 50% Sepharose 4B/25% Pansorbin (Pharmacia and Calbiochem, respectively) and HA-PKBα immunoprecipitated from 1 mg of extract using the 12CA5 antibody coupled to Protein A Sepharose beads. Immunoprecipitates were washed twice with lysis buffer containing 0.5 M NaCl and once with

1 lysis buffer.

WO 97/22360

Immunoblotting and quantification of levels of PKBα expression. Cell extracts were resolved by 7.5% SDS-PAGE and transferred to Immobilon membranes (Millipore). Filters were blocked for 30 min in a blocking buffer containing 5% skimmed milk in 1x TBS, 1% Triton X-100 and 0.5% Tween 20, followed by a 2h incubation with the 12CA5 supernatant 1000-fold diluted in the same buffer. The secondary antibody was alkaline conjugated anti-mouse Ig from goat (Southern Biotechnology Associates, Inc), 1000-fold diluted in the blocking buffer. Detection was performed using AP colour development reagents from Bio-Rad according to the manufacturer's instructions. Quantification of levels of PKBα expression was achieved by chemiluminescence, using fluroisothiocyanante-labelled antimouse IgG from goat as the secondary antibody and the Storm 840/860 and ImageQuant software from Molecular Dynamics.

PCT/GB96/03186

All peptides used to assay PKBa, and TTYADFIASGRTGRRNAIHD (the specific peptide inhibitor of cyclic AMP dependent protein kinase - PKI) were synthesised on an Applied Biosystems 431A peptide synthesizer. Their purity (> 95%) was established by HPLC and electrospray mass spectrometry, and their concentrations were determined by quantitative amino acid analysis.

Preparation and assay of PKBa. The construction of cytomegalovirus vectors (pCMV5) of the human haemagglutonin epitope-tagged wild type $_{(HA-PKB\alpha)}$ was described previously (Alessi et al., 1996). 293 cells grown on 10 cm dishes were transfected with a DNA construct expressing $HA-PKB\alpha$ using a modified calcium phosphate procedure (Alessi et al., 1996). The cells were deprived of serum for 16h prior to lysis and, where indicated, were stimulated for 10 min in the presence of 50 ng/ml IGF-1 to activate PKB α . The cells were lysed in 1.0 ml ice-cold Buffer A (50 mM Tris/HCl pH 7.5, 1 mM EDTA 1 mM EGTA, 1% (by vol) Triton X-100, 1 mM sodium orthovanadate, 10 mM sodium β -glycerophosphate, 50 mM NaF, 5 mM sodium pyrophosphate, 1 μ M Microcystin-LR, 0.27 M sucrose, 1 mM benzamidine, 0.2 mM phenylmethylsulphonyl fluoride, 10 μ g/ml leupeptin, and 0.1 % (by vol) 2-mercaptoethanol) the lysate centrifuged at 4° C for 10 min at 13, 000 x g and the supernatant obtained from one 10 cm dish of cells (2-3 mg protein) was incubated for 60 min on a shaking platform with 20 μ l of protein G-Sepharose coupled to 10 $\mu \mathrm{g}$ of HA monoclonal antibody. The suspension was centrifuged for 1 min at 13, 000 x g, the Protein

G-Sepharose-antibody-HA-PKBa complex washed twice with 1.0 ml of Buffer A containing 0.5 M NaCl, and twice with Buffer B (50 mM Tris/HCl pH 7.5, 0.1 mM EGTA, 0.01% (by vol) Brij-35 and 0.1% (by vol) 2-mercaptoethanol). The PKBa immunoprecipitates were diluted in Buffer B to an activity of 2.0 U/ml towards the Crosstide peptide GRPRTSSFAEG and 0.1 ml aliquots snap frozen in liquid nitrogen and stored at -80 oC. No significant loss of PKBa activity occurred upon thawing the PKBa immunoprecipitates or during storage at -80oC for up to 3 months . The standard PKB α assay (50 μ l) contained: 50 mM Tris/HCl pH 7.5, 0.1 mM EGTA, 0.1% (by vol) 2-mercaptoethanol, 2.5 \(\mu\)M PKI, 0.2 U/ml PKB\(\alpha\), Crosstide (30 μ M), 10 mM magnesium acetate and 0.1 mM [γ^{32} P]ATP (100-200 cpm/pmol). The assays were carried out for 15 min at 30oC, the assay tubes being agitated continuously to keep the immunoprecipitate in suspension, then terminated and analysed as described (Alessi et al., 1995). One unit of activity was that amount of enzyme which catalysed the phosphorylation of 1 nmol of Crosstide in 1 min. The phosphorylation of other peptides, histone H2B and MBP were carried out in an identical manner. All the Crosstide activity in HA-PKBa immunoprecipitates is catalysed by PKB α (see Results) and the PKB α concentration in the immunoprecipitates was estimated by densitometric scanning of Coomassie blue-stained polyacrylamide gels, using bovine serum albumin as a standard. Protein concentrations were determined by the method of Bradford using bovine serum albumin as standard (Bradford et al., 1976). Michaelis constants (Km) and Vmax values were determined from double reciprocal plots of 1/V against 1/S, where V is the initial rate of phosphorylation, and S is the substrate concentration. The standard errors for all reported kinetic constants were within < ± 20%, and the data is reported as mean values for 3 independent determinations. Fig 16 shows the results relative to those obtained for unstimulated PKBa.

Tryptic digestion of histons 2B phosphorylated by PKB α . Histone H2B (30 μ M) was phosphorylated with 0.2 U/ml HA-PKB α . After 60 min 0.2 vol of 100% (by mass) trichloroacetic acid was added, and the sample incubated for 1 h on ice. The suspension was centrifuged for 10 min at 13, 000 x g, the supernatant discarded and the pellet washed five times with 0.2 ml of ice cold acetone. The pellet was resuspended in 0.3 ml of 50 mM Tris/HCl pH 8.0, 0.1% (by vol) reduced Triton-X100 containing 2 μ g of alkylated trypsin and, after incubation for 16 h at 30oC, the digest was centrifuged for 5 min at 13, 000 x g. The supernatant, containing 95% of the

57

 ^{32}P -radioactivity, was chromatographed on a Vydac C18 column 1 equilibrated with 0.1% (by vol) trifluoroacetic acid (TFA) in 2 water. With reference to the results shown in Fig 17, the columns 3 were developed with a linear acetonitrile gradient (diagonal line) 4 at a flow rate of 0.8 ml / min and fractions of 0.4 ml were 5 collected. (A) Tryptic peptide map of "P-labelled histone H2B, 6 70% of the radioactivity applied to the column was recovered from 7 the major ³²P-peptide eluting at 19.5% acetonitrile. (B) A portion 8 of the major "P-peptide (50 pmol) was analysed on an Applied 9 Biosystems 476A sequencer, and the phenylthiohydantoin (Pth) amino 10 acids identified after each cycle of Edman degradation are shown 11 using the single letter code for amino acids. A portion of the 12 major "P-peptide (1000 cpm) was then coupled covalently to a 13 Sequelon arylamine membrane and analysed on an Applied Biosystems 14 470A sequencer using the modified programme described in (Stokoe 15 et al., 1992). ³²P radioactivity was measured after each cycle of 16 Edman degradation. 17

58

Table 7.1
Molecular basis for the substrate specificity of PKBα

The phosphorylated residue is shown in boldface type, the altered residue is underlined. $V(100 \mu M)$ is the relative rate of phosphorylation at 0.1 mM peptide relative to peptide 1. ND, not determined. *An alanine residue was added to the C-terminal of the peptide RPRTSSP, since we have experienced difficulty in synthesing peptides terminating in proline.

1 Claims: 2 The use of a composition of PKB, its analogues, 3 isoforms, inhibitors, activators and/or the functional 4 equivalents thereof, to regulate glycogen metabolism 5 and/or protein synthesis. 6 7 The use of a composition of PKB, its analogues, 8 isoforms, inhibitors, activators and/or the functional 9 equivalents thereof, for the manufacture of a 10 medicament to regulate glycogen metabolism and/or 11 protein synthesis. 12 13 The use as claimed in claim 1 or claim 2, to 14 combat disease states where glycogen metabolism and/or 15 protein synthesis exhibits abnormality. 16 17 The use as claimed in claim 1, 2 or 3, to combat 18 diabetes. 19 20 The use as claimed in any preceding claim, to 21 combat cancer. 22 23 The use as claimed in claim 5, wherein the cancer 24 is breast, pancreatic or ovarian cancer. 25 26 The use as claimed in any preceding claim, wherein 27 the PKB is PKBlpha, eta or γ , an analogue, isoform, 28 inhibitor, activator or a functional equivalent 29 thereof. 30 31 The use as claimed in any preceding claim, wherein 32 8 the PKB, its analogue, isoform, or functional 33 equivalent is modified at one or both of amino acids 34 308 and 473 by phosphorylation and/or mutation. 35 36

PCT/GB96/03186 WO 97/22360

66

A composition of PKB, its analogues, isoforms, 1 9 inhibitors, activators and/or the functional 2 equivalents thereof. 3 4 A peptide having or including the amino acid 10 5 sequence Arg-Xaa-Arg-Yaa-Zaa-Ser/Thr-Hyd, where Xaa is 6 any amino acid, Yaa and Zaa are any amino acid, and Hyd 7 is a large hydrophobic residue, or a functional 8 equivalent of such a peptide. 9 10 A peptide as claimed in claim 10, wherein Hyd is 11 11 Phe or Leu, or a functional equivalent thereof. 12 13 A peptide as claimed in claim 10 or claim 11, 14 12 wherein Yaa or Zaa or both are an amino acid other than 15 glycine. 16 17 A peptide as claimed in claim 10, having the amino 18 acid sequence GRPRTSSFAEG, or a functional equivalent 19 thereof. 20 21 A method of identifying agents able to influence 22 14 the activity of GSK3, said method comprising: 23 24 exposing a test substance to a substrate of GSK3; 25 a. 26 and 27 detecting whether said substrate has been b. phosphorylated. 28 29 A method of identifying agents which influence the 30 15 activity of PKB, comprising: 31 32 exposing a test substance to a sample containing a. 33 PKB, to form a mixture; 34 exposing said mixture to a peptide as claimed in 35

claim 10, 11, 12 or 13; and

b.

detecting whether (and, optionally, to what c. extent) said peptide has been phosphorylated. A method as claimed in claim 14 or 15, wherein the extent of phosphorylation of the peptide is determined. A method as claimed in claim 15, wherein the phosphorylation state(s) of one or both of amino acids 308 and 473 on PKB is determined. A method as claimed in any one of claims 14 to 17, wherein the test substance is an analogue, isoform, inhibitor, or activator of PKB. A method as claimed in any one of claims 14 to 18, wherein steps a or b (or both) are carried out in the presence of divalent cations and ATP. A method of treatment of the human or non-human animal body, said method comprising administering PKB, its analogues, inhibitors, stimulators or functional equivalents thereof to said body. A method as claimed in claim 20, to combat disease states where glycogen metabolism and/or protein synthesis exhibits abnormality. A method as claimed in claim 20 or 21, to combat diabetes. A method as claimed in claim 20 or 22, to combat cancer.

24 A method as claimed in claim 23, wherein the cancer is breast, pancreatic or ovarian cancer.

PCT/GB96/03186 WO 97/22360

68

A method as claimed in any one of claims 20 to 24, 25 1 wherein the PKB is PKB α , β or γ , an analogue, isoform, 2 inhibitor, activator or a functional equivalent 3 thereof. An agent capable of influencing the activity of 26 б PKB, its isoforms, analogues and/or functional 7 equivalents, by modifying amino acids 308 and/or 473 by 8 phosphorylation or mutation. 9 10 A method of determining the ability of a substance 27 11 to affect the activity or activation of PKB, the method 12 comprising exposing the substance to PKB and 13 phosphatidyl inositol polyphosphate and determining the 14 interaction between PKB and the phosphatidyl inositol 15 polyphosphate. 16 17 A method of determining the ability of a substance 28 18 to combat diabetes, cancer, or any disorder which 19 involves irregularity of protein synthesis or glycogen 20 metabolism, the method comprising exposing the 21 substance to PKB and phosphatidyl inositol 22 polyphosphate and determining the interaction between 23 PKB and the phosphatidyl inositol polyphosphate. 24 25 A method as claimed in claim 27 or claim 28, 29 26 wherein the interaction between PKB and the 27 phosphatidyl inositol polyphosphate is measured by 28 assessing the phosphorylation state of PKB. 29 30 A method as claimed in claim 29, wherein the 31 30 phosphorylation state of PKB at T308 and/or S473 is 32 assessed. 33

34

A method of identifying activators or inhibitors 31 35 of GSK3 comprising exposing the substance to be tested 36

69

to GSK3 and determining the state of activation of 1 2 GSK3. 3 A method as claimed in claim 31 wherein the state 4 of activation of GSK3 is determined by assessing its 5 phosphorylation. 6 7 A method of determining the suitability of a test 8 substance for use in combatting diabetes, cancer, or 9 any disorder which involves irregularity of protein 10 synthesis or glycogen metabolism, the method comprising 11 exposing the substance to be tested to GSK3 and 12 determining the state of activation of GSK3. 13 14 A method for screening for inhibitors or 15 34 activators of enzymes that catalyse the phosphorylation 16 of PKB, the method comprising exposing the substance to 17 be tested to 18 - one or more enzymes upstream of PKB; 19 - PKB; and (optionally) 20 - nucleoside triphosphate 21 and determining whether (and optionally to what extent) 22

the PKB has been phosphorylated on T308 and/or S473.

Published

With international search report.

Before the expiration of the time limit for amending the claims and to be republished in the event of the receipt of amendments.

(88) Date of publication of the international search report: 31 July 1997 (31.07.97)

- (54) Title: CONTROL OF PROTEIN SYNTHESIS, AND SCREENING METHOD FOR AGENTS
- (57) Abstract

A method for screening for agents capable of affecting the activity of kinases GSK3 and PKB is disclosed. The method involves assessing the phosphorylation of PKB on two amino acids on the PKB molecule particularly.

rnational application No.

PCT/GB 96/03186

Box i Ob	servations where certain claims were found unsearchable (Continuation of item 1 of first sheet)
This Interna	tional Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:
Re is tr ba	ims Nos.: 1,3-8,20-25 ause they relate to subject matter not required to be searched by this Authority, namely: mark: Although claims 1,3-8 (all partially, as far as an in vivo method concerned), and 20 to 25 (all completely) are directed to a method of eatment of the human/animal body, the search has been carried out and sed on the alleged effects of the compound/composition. Ims Nos.: Ims Nos.: Buse they relate to parts of the International Application that do not comply with the prescribed requirements to such extent that no meaningful International Search can be carried out, specifically:
3. Clai	ms Nos.; use they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).
Box II Ob	servations where unity of invention is lacking (Continuation of item 2 of first sheet)
This Internat	ional Searching Authority found multiple inventions in this international application, as follows:
1. As a	all required additional search fees were timely paid by the applicant, this International Search Report covers all chable claims.
2. As a of a	Il searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment ny additional fee.
3. As cove	only some of the required additional search fees were timely paid by the applicant, this International Search Report rs only those claims for which fees were paid, specifically claims Nos.:
4. No restu	required additional search fees were timely paid by the applicant. Consequently, this International Search Report is international Search Report in the claims; it is covered by claims Nos.;
Remark on Pi	The additional search fees were accompanied by the applicant's protest. No protest accompanied the payment of additional search fees.
